Package ‘dartR’

October 13, 2022

Type Package

Title Importing and Analysing SNP and Silicodart Data Generated by Genome-Wide Restriction Fragment Analysis

Version 2.0.4

Date 2022-06-03

Description Functions are provided that facilitate the import and analysis of SNP (single nucleotide polymorphism) and silicodart (presence/absence) data. The main focus is on data generated by DarT (Diversity Arrays Technology). However, once SNP or related fragment presence/absence data from any source is imported into a genlight object many of the functions can be used. Functions are available for input and output of SNP and silicodart data, for reporting on and filtering on various criteria (e.g. CallRate, Heterozygosity, Reproducibility, maximum allele frequency). Advanced filtering is based on Linkage Disequilibrium and HWE (Hardy-Weinberg equilibrium). Other functions are available for visualization after PCoA (Principle Coordinate Analysis), or to facilitate transfer of data between genlight/genind objects and newhybrids, related, phylip, structure, faststructure packages.

**Description**

This a test data set to test the validity of functions within dartR and is based on a DArT SNP data set of simulated bandicoots across Australia. It contains 96 individuals and 1000 SNPs.

**Usage**

```r
bandicoot.gl
```

**Format**

genlight object

**Author(s)**

Bernd Gruber (bugs? Post to https://groups.google.com/d/forum/dartr

---

**gi2gl**

*A genlight object created via the read.dart functions*

**Description**

Converts a genind object into a genlight object

**Usage**

```r
gi2gl(gi, parallel = FALSE, verbose = NULL)
```
Arguments

- **gi**: A genind object [required].
- **parallel**: Switch to deactivate parallel version. It might not be worth to run it parallel most of the times [default: FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default: 2].

Details

Be aware due to ambiguity which one is the reference allele a combination of gi2gl(gl2gi(gl)) does not return an identical object (but in terms of analysis this conversions are equivalent)

Value

A genlight object, with all slots filled.

Author(s)

Bernd Gruber (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

---

**gl.alf**

Calculates allele frequency of the first and second allele for each loci
A very simple function to report allele frequencies

Description

Calculates allele frequency of the first and second allele for each loci
A very simple function to report allele frequencies

Usage

gl.alf(x)

Arguments

- **x**: Name of the genlight object containing the SNP data [required].

Value

A simple data.frame with alf1, alf2.

Author(s)

Bernd Gruber (bugs? Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))
Examples

```r
# for the first 10 loci only
gl.alf(possums.gl[,1:10])
barplot(t(as.matrix(gl.alf(possums.gl[,1:10]))))
```

---

`gl.amova`  
*Performs AMOVA using genlight data*

Description

This script performs an AMOVA based on the genetic distance matrix from `stamppNeisD()` [package StAMPP] using the `amova()` function from the package PEGAS for exploring within and between population variation. For detailed information use their help pages: `?pegas::amova`, `?StAMPP::stamppAmova`. Be aware due to a conflict of the `amova` functions from various packages I had to ‘hack’ `StAMPP::stamppAmova` to avoid a namespace conflict.

Usage

```r
gl.amova(x, distance = NULL, permutations = 100, verbose = NULL)
```

Arguments

- **x**: Name of the genlight containing the SNP genotypes, with population information [required].
- **distance**: Distance matrix between individuals (if not provided `NeisD` from `StAMPP::stamppNeisD` is calculated) [default NULL].
- **permutations**: Number of permutations to perform for hypothesis testing [default 100]. Please note should be set to 1000 for analysis.
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2, unless specified using `gl.set.verbosity`].

Value

An object of class ‘amova’ which is a list with a table of sums of square deviations (SSD), mean square deviations (MSD), and the number of degrees of freedom, and a vector of variance components.

Author(s)

Bernd Gruber (bugs? Post to https://groups.google.com/d/forum/dartr)

Examples

```r
# permutations should be higher, here set to 10 because of speed
out <- gl.amova(bandicoot.gl, permutations=10)
```
gl.assign.mahalanobis

Assign an individual of unknown provenance to population based on Mahalanobis Distance

Description

This script assigns an individual of unknown provenance to one or more target populations based on the unknown individual’s proximity to population centroids; proximity is estimated using Mahalanobis Distance.

The following process is followed:

1. An ordination is undertaken on the populations to again yield a series of orthogonal (independent) axes.
2. A workable subset of dimensions is chosen, that specified, or equal to the number of dimensions with substantive eigenvalues, whichever is the smaller.
3. The Mahalobalis Distance is calculated for the unknown against each population and probability of membership of each population is calculated. The assignment probabilities are listed in support of a decision.

Usage

```r
gl.assign.mahalanobis(
  x, 
  dim.limit = 2, 
  plevel = 0.999, 
  plot.out = TRUE, 
  unknown, 
  verbose = NULL
)
```

Arguments

- **x**: Name of the input genlight object [required].
- **dim.limit**: Maximum number of dimensions to consider for the confidence ellipses [default 2].
- **plevel**: Probability level for bounding ellipses [default 0.999].
- **plot.out**: If TRUE, produces a plot showing the position of the unknown in relation to putative source populations [default TRUE].
- **unknown**: Identity label of the focal individual whose provenance is unknown [required].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
Details

There are three considerations to assignment. First, consider only those populations for which the unknown has no private alleles. Private alleles are an indication that the unknown does not belong to a target population (provided that the sample size is adequate, say >=10). This can be evaluated with `gl.assign.pa()`.

A next step is to consider the PCoA plot for populations where no private alleles have been detected. The position of the unknown in relation to the confidence ellipses is plotted by this script as a basis for narrowing down the list of putative source populations. This can be evaluated with `gl.assign.pca()`.

The third step (delivered by this script) is to consider the assignment probabilities based on the squared Generalised Linear Distance (Mahalanobis distance) of the unknown from the centroid for each population, then to consider the probability associated with its quantile using the Chisquare approximation. In effect, this index takes into account position of the unknown in relation to the confidence envelope in all selected dimensions of the ordination. The larger the assignment probability, the greater the confidence in the assignment.

If `dim.limit` is set to 2, to correspond with the dimensions used in `gl.assign.pa()`, then the output provides a ranking of the final set of putative source populations. If `dim.limit` is set to be > 2, then this script provides a basis for further narrowing the set of putative populations. If the unknown individual is an extreme outlier, say at less than 0.001 probability of population membership (0.999 confidence envelope), then the associated population can be eliminated from further consideration.

Warning: `gl.assign.mahal()` treats each specified dimension equally, without regard to the percentage variation explained after ordination. If the unknown is an outlier in a lower dimension with an explanatory variance of, say, 0.1 dimensions from the ordination.

Each of these above approaches provides evidence, none are 100% They need to be interpreted cautiously.

In deciding the assignment, the script considers an individual to be an outlier with respect to a particular population at alpha = 0.001 as default

Value

A data frame with the results of the assignment analysis.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

```r
## Not run:
#Test run with a focal individual from the Macleay River (EmmacMaclGeor)
test <- gl.assign.pa(testset.gl, unknown='UC_01044', nmin=10, threshold=1, verbose=3)
test_2 <- gl.assign.pca(test, unknown='UC_01044', plevel=0.95, verbose=3)
df <- gl.assign.mahalanobis(test_2, unknown='UC_01044', verbose=3)
```

## End(Not run)
gl.assign.pa

Eliminates populations as possible source populations for an individual of unknown provenance, using private alleles

Description

This script eliminates from consideration as putative source populations, those populations for which the individual has too many private alleles. The populations that remain are putative source populations, subject to further consideration.

The algorithm identifies those target populations for which the individual has no private alleles or for which the number of private alleles does not exceed a user specified threshold.

An excessive count of private alleles is an indication that the unknown does not belong to a target population (provided that the sample size is adequate, say >=10).

Usage

```r
gl.assign.pa(
  x, unknown,
  nmin = 10, threshold = 0,
  n.best = NULL,
  verbose = NULL
)
```

Arguments

- `x` Name of the input genlight object [required].
- `unknown` SpecimenID label (indName) of the focal individual whose provenance is unknown [required].
- `nmin` Minimum sample size for a target population to be included in the analysis [default 10].
- `threshold` Populations to retain for consideration; those for which the focal individual has less than or equal to threshold loci with private alleles [default 0].
- `n.best` If given a value, dictates the best `n=n.best` populations to retain for consideration (or more if their are ties) based on private alleles [default NULL].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

A genlight object containing the focal individual (assigned to population ‘unknown’) and populations for which the focal individual is not distinctive (number of loci with private alleles less than or equal to the threshold). If no such populations, the genlight object contains only data for the unknown individual.
gl.assign.pca

Author(s)

gl.assign.pca

Examples

# Test run with a focal individual from the Macleay River (EmmacMaclGeor)
test <- gl.assign.pa(testset.gl, unknown='UC_00146', nmin=10, threshold=1,
verbose=3)

Description

This script assigns an individual of unknown provenance to one or more target populations based on its proximity to each population defined by a confidence ellipse in ordinated space of two dimensions.

The following process is followed:

1. The space defined by the loci is ordinated to yield a series of orthogonal axes (independent), and the top two dimensions are considered. Populations for which the unknown lies outside the specified confidence limits are no longer removed from the dataset.

Usage

gl.assign.pca(x, unknown, plevel = 0.999, plot.out = TRUE, verbose = NULL)

Arguments

x Name of the input genlight object [required].
unknown Identity label of the focal individual whose provenance is unknown [required].
plevel Probability level for bounding ellipses in the PCoA plot [default 0.999].
plot.out If TRUE, plot the 2D PCA showing the position of the unknown [default TRUE]
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
Details

There are three considerations to assignment. First, consider only those populations for which the unknown has no private alleles. Private alleles are an indication that the unknown does not belong to a target population (provided that the sample size is adequate, say >=10). This can be evaluated with gl.assign.pa().

A next step is to consider the PCoA plot for populations where no private alleles have been detected and the position of the unknown in relation to the confidence ellipses as is plotted by this script. Note, this plot is considering only the top two dimensions of the ordination, and so an unknown lying outside the confidence ellipse can be unambiguously interpreted as it lying outside the confidence envelope. However, if the unknown lies inside the confidence ellipse in two dimensions, then it may still lie outside the confidence envelope in deeper dimensions. This second step is good for eliminating populations from consideration, but does not provide confidence in assignment.

The third step is to consider the assignment probabilities, using the script gl.assign.mahalanobis(). This approach calculates the squared Generalised Linear Distance (Mahalanobis distance) of the unknown from the centroid for each population, and calculates the probability associated with its quantile under the zero truncated normal distribution. This index takes into account position of the unknown in relation to the confidence envelope in all selected dimensions of the ordination.

Each of these approaches provides evidence, none are 100 need to be interpreted cautiously. They are best applied sequentially.

In deciding the assignment, the script considers an individual to be an outlier with respect to a particular population at alpha = 0.001 as default.

Value

A genlight object containing only those populations that are putative source populations for the unknown individual.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

```r
## Not run:
# Test run with a focal individual from the Macleay River (EmmacMaclGeor)
test <- gl.assign.pa(testset.gl, unknown='UC_00146', nmin=10, threshold=1, verbose=3)
test_2 <- gl.assign.pca(test, unknown='UC_00146', plevel=0.95, verbose=3)
## End(Not run)
```
gl.basic.stats  
*Calculates basic statistics for each loci (Hs, Ho, Fis etc.)*

**Description**

Based on function `basic.stats`. Check `?basic.stats` for help.

**Usage**

```r
gl.basic.stats(x, digits = 4, verbose = NULL)
```

**Arguments**

- **x**: Name of the genlight object containing the SNP data [required].
- **digits**: Number of digits that should be returned [default 4].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using `gl.set.verbosity`].

**Value**

Several tables and lists with all basic stats. `basic.stats` for details.

**Author(s)**

Bernd Gruber (bugs? Post to https://groups.google.com/d/forum/dartr)

**Examples**

```r
out <- gl.basic.stats(possums.gl)
```

---

**gl.blast**

*Aligns nucleotides sequences against those present in a target database using blastn*

**Description**

Basic Local Alignment Search Tool (BLAST; Altschul et al., 1990 & 1997) is a sequence comparison algorithm optimized for speed used to search sequence databases for optimal local alignments to a query. This function creates fasta files, creates databases to run BLAST, runs blastn and filters these results to obtain the best hit per sequence.

This function can be used to run BLAST alignment of short-read (DArTseq data) and long-read sequences (Illumina, PacBio... etc). You can use reference genomes from NCBI, genomes from your private collection, contigs, scaffolds or any other genetic sequence that you would like to use as reference.
Usage

```r
gl.blast(
  x,
  ref_genome,
  task = "megablast",
  Percentage_identity = 70,
  Percentage_overlap = 0.8,
  bitscore = 50,
  number_of_threads = 2,
  verbose = NULL
)
```

Arguments

- **x**: Either a genlight object containing a column named 'TrimmedSequence' containing the sequence of the SNPs (the sequence tag) trimmed of adapters as provided by DArT; or a path to a fasta file with the query sequences [required].
- **ref_genome**: Path to a reference genome in fasta of fna format [required].
- **task**: Four different tasks are supported: 1) “megablast”, for very similar sequences (e.g. sequencing errors), 2) “dc-megablast”, typically used for inter-species comparisons, 3) “blastn”, the traditional program used for inter-species comparisons, 4) “blastn-short”, optimized for sequences less than 30 nucleotides [default ‘megablast’].
- **Percentage_identity**: Not a very sensitive or reliable measure of sequence similarity, however it is a reasonable proxy for evolutionary distance. The evolutionary distance associated with a 10 percent change in Percentage_identity is much greater at longer distances. Thus, a change from 80 – 70 percent identity might reflect divergence 200 million years earlier in time, but the change from 30 percent to 20 percent might correspond to a billion year divergence time change [default 70].
- **Percentage_overlap**: Calculated as alignment length divided by the query length or subject length (whichever is shortest of the two lengths, i.e. length / min(qlen,slen)) [default 0.8].
- **bitscore**: A rule-of-thumb for inferring homology, a bit score of 50 is almost always significant [default 50].
- **number_of_threads**: Number of threads (CPUs) to use in blastn search [default 2].
- **verbose**: verbose= 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity]

Details

**Installing BLAST**

It is important to install BLAST in a path that does not contain spaces for this function to work.

**Running BLAST**

Four different tasks are supported:

- “megablast”, for very similar sequences (e.g. sequencing errors)
- “dc-megablast”, typically used for inter-species comparisons
- “blastn”, the traditional program used for inter-species comparisons
- “blastn-short”, optimized for sequences less than 30 nucleotides

If you are running a BLAST alignment of similar sequences, for example Turtle Genome Vs Turtle Sequences, the recommended parameters are: task = “megablast”, Percentage_identity = 70, Percentage_overlap = 0.8 and bitscore = 50.

If you are running a BLAST alignment of highly dissimilar sequences because you are probably looking for sex linked hits in a distantly related species, and you are aligning for example sequences of Chicken Genome Vs Bassiana, the recommended parameters are: task = “dc-megablast”, Percentage_identity = 50, Percentage_overlap = 0.01 and bitscore = 30.

Be aware that running BLAST might take a long time (i.e. days) depending of the size of your query, the size of your database and the number of threads selected for your computer.

**BLAST output**

The BLAST output is formatted as a table using output format 6, with columns defined in the following order:

- qseqid - Query Seq-id
- sacc - Subject accession
- stitle - Subject Title
- qseq - Aligned part of query sequence
- sseq - Aligned part of subject sequence
- nident - Number of identical matches
- mismatch - Number of mismatches
- pident - Percentage of identical matches
- length - Alignment length
- evalue - Expect value
- bitscore - Bit score
- qstart - Start of alignment in query
- qend - End of alignment in query
- sstart - Start of alignment in subject
- send - End of alignment in subject
- gapopen - Number of gap openings
- gaps - Total number of gaps
- qlen - Query sequence length
- slen - Subject sequence length
Databases containing unfiltered aligned sequences, filtered aligned sequences and one hit per sequence are saved to the temporal directory (tempdir) and can be accessed with the function `gl.print.reports` and listed with the function `gl.list.reports`. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

**BLAST filtering**

BLAST output is filtered by ordering the hits of each sequence first by the highest percentage identity, then the highest percentage overlap and then the highest bitscore. Only one hit per sequence is kept based on these selection criteria.

**Value**

If the input is a genlight object: returns a genlight object with one hit per sequence merged to the slot $other$loc.metrics. If the input is a fasta file: returns a dataframe with one hit per sequence.

```r
## Not run:
res <- gl.blast(x= testset.gl, ref_genome = 'sequence.fasta')
# display of reports saved in the temporal directory
gl.print.reports()
# open the reports saved in the temporal directory
blast_databases <- gl.print.reports(1)
## End(Not run)
```
gl.check.verbosity

Checks the current global verbosity

Description

The verbosity can be set in one of two ways – (a) explicitly by the user by passing a value using the parameter verbose= in a function, or (b) by setting the verbosity globally as part of the r environment (gl.set.verbosity).

Usage

`gl.check.verbosity(x = NULL)`

Arguments

x

User requested level of verbosity [default NULL].

Value

The verbosity, in variable verbose

Author(s)

Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

---

gl.collapse

Collapses a distance matrix by amalgamating populations with pairwise fixed difference count less that a threshold

Description

This script takes a file generated by gl.fixed.diff and amalgamates populations with distance less than or equal to a specified threshold. The distance matrix is generated by gl.fixed.diff().

The script then applies the new population assignments to the genlight object and recalculates the distance and associated matrices.

Usage

`gl.collapse(fd, tpop = 0, tloc = 0, pb = FALSE, verbose = NULL)`
**Arguments**

- **fd**
  Name of the list of matrices produced by `gl.fixed.diff()` [required].
- **tpop**
  Threshold number of fixed differences above which populations will not be amalgamated [default 0].
- **tloc**
  Threshold defining a fixed difference (e.g. 0.05 implies 95:5 vs 5:95 is fixed) [default 0].
- **pb**
  If TRUE, show a progress bar on time consuming loops [default FALSE].
- **verbose**
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`]

**Value**

A list containing the `gl` object `x` and the following square matrices:

1. $gl$ – the new genlight object with populations collapsed;
2. $fd$ – raw fixed differences;
3. $pcfd$ – percent fixed differences;
4. $nobs$ – mean no. of individuals used in each comparison;
5. $nloc$ – total number of loci used in each comparison;
6. $expfpos$ – NA’s, populated by `gl.fixed.diff` [by simulation]
7. $expfpos$ – NA’s, populated by `gl.fixed.diff` [by simulation]
8. $prob$ – NA’s, populated by `gl.fixed.diff` [by simulation]

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**Examples**

```r
fd <- gl.fixed.diff(testset.gl,tloc=0.05)
fd
fd2 <- gl.collapse(fd,tpop=1)
fd2
fd3 <- gl.collapse(fd2,tpop=1)
fd3
```
gl.compliance.check

Checks a genlight object to see if it complies with dartR expectations and amends it to comply if necessary

Description

This function will check to see that the genlight object conforms to expectation in regard to dartR requirements (see details), and if it does not, will rectify it.

Usage

gl.compliance.check(x, verbose = NULL)

Arguments

x
Name of the input genlight object [required].

verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

A genlight object used by dartR has a number of requirements that allow functions within the package to operate correctly. The genlight object comprises:

1. The SNP genotypes or Tag Presence/Absence data (SilicoDArT);
2. An associated dataframe (gl@other$loc.metrics) containing the locus metrics (e.g. Call Rate, Repeatability, etc);
3. An associated dataframe (gl@other$ind.metrics) containing the individual/sample metrics (e.g. sex, latitude (=lat), longitude(=lon), etc);
4. A specimen identity field (indNames(gl)) with the unique labels applied to each individual/sample;
5. A population assignment (popNames) for each individual/specimen;
6. Flags that indicate whether or not calculable locus metrics have been updated.

Value

A genlight object that conforms to the expectations of dartR

Author(s)

Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

Examples

x <- gl.compliance.check(testset.gl)
x <- gl.compliance.check(testset.gs)
gl.costdistances

Calculates cost distances for a given landscape (resistance matrix)

Description

Calculates a cost distance matrix, to be used with run.popgensim.

Usage

```r
gl.costdistances(landscape, locs, method, NN, verbose = NULL)
```

Arguments

- **landscape**: A raster object coding the resistance of the landscape [required].
- **locs**: Coordinates of the subpopulations. If a genlight object is provided coordinates are taken from @other$latlon and centers for population (pop(gl)) are calculated. In case you want to calculate costdistances between individuals redefine pop(gl) via: `pop(gl) <- indNames(gl)` [required].
- **method**: Defines the type of cost distance, types are 'leastcost', 'rSPDistance' or 'commune' (Circuitscape type) [required].
- **NN**: Number of next neighbours recommendation is 8 [required].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

A costdistance matrix between all pairs of locs.

Examples

```r
## Not run:
data(possums.gl)
library(raster) #needed for that example
landscape.sim <- readRDS(system.file('extdata','landscape.sim.rdata', package='dartR'))
#calculate mean centers of individuals per population
xy <- apply(possums.gl@other$xy, 2, function(x) tapply(x, pop(possums.gl), mean))
cd <- gl.costdistances(landscape.sim, xy, method='leastcost', NN=8)
round(cd,3)
## End(Not run)
```
gl.define.pop

Defines a new population in a genlight object for specified individuals

Description

The script reassigns existing individuals to a new population and removes their existing population assignment.

The script returns a genlight object with the new population assignment.

Usage

```r
gl.define.pop(x, ind.list, new, verbose = NULL)
```

Arguments

- `x` Name of the genlight object containing SNP genotypes [required].
- `ind.list` A list of individuals to be assigned to the new population [required].
- `new` Name of the new population [required].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`].

Value

A genlight object with the redefined population structure.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

```r
popNames(testset.gl)
gl <- gl.define.pop(testset.gl, ind.list=c('AA019073','AA004859'), new='newguys')
popNames(gl)
indNames(gl)[pop(gl)=='newguys']
```
gl.diagnostics.hwe

Provides descriptive stats and plots to diagnose potential problems with Hardy-Weinberg proportions

Description

Different causes may be responsible for lack of Hardy-Weinberg proportions. This function helps diagnose potential problems.

Usage

```r
gl.diagnostics.hwe(
  x,
  alpha_val = 0.05,
  bins = 20,
  stdErr = TRUE,
  colors_hist = two_colors,
  colors_barplot = two_colors_contrast,
  plot_theme = theme_dartR(),
  save2tmp = FALSE,
  n.cores = "auto",
  verbose = NULL
)
```

Arguments

- `x`: Name of the genlight object containing the SNP data [required].
- `alpha_val`: Level of significance for testing [default 0.05].
- `bins`: Number of bins to display in histograms [default 20].
- `stdErr`: Whether standard errors for Fis and Fst should be computed (default: TRUE)
- `colors_hist`: List of two color names for the borders and fill of the histogram [default two_colors].
- `colors_barplot`: Vector with two color names for the observed and expected number of significant HWE tests [default two_colors_contrast].
- `plot_theme`: User specified theme [default theme_dartR()].
- `save2tmp`: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- `n.cores`: The number of cores to use. If "auto" [default], it will use all but one available cores.
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].
Details

This function initially runs `gl.report.hwe` and reports the ternary plots. The remaining outputs follow the recommendations from Waples (2015) paper and De Meeûs 2018. These include:

1. A histogram with the distribution of p-values of the HWE tests. The distribution should be roughly uniform across equal-sized bins.

2. A bar plot with observed and expected (null expectation) number of significant HWE tests for the same locus in multiple populations (that is, the x-axis shows whether a locus results significant in 1, 2, ..., n populations. The y-axis is the count of these occurrences. The zero value on x-axis shows the number of non-significant tests). If HWE tests are significant by chance alone, observed and expected number of HWE tests should have roughly a similar distribution.

3. A scatter plot with a linear regression between Fst and Fis, averaged across subpopulations. De Meeûs 2018 suggests that in the case of Null alleles, a strong positive relationship is expected (together with the Fis standard error much larger than the Fst standard error, see below). **Note**, this is not the scatter plot that Waples 2015 presents in his paper. In the lower right corner of the plot, the Pearson correlation coefficient is reported.

4. The Fis and Fst (averaged over loci and subpopulations) standard errors are also printed on screen and reported in the returned list (if stdErr=TRUE). These are computed with the Jackknife method over loci (See De Meeûs 2007 for details on how this is computed) and it may take some time for these computations to complete. De Meeûs 2018 suggests that under a global significant heterozygosity deficit: - if the correlation between Fis and Fst is strongly positive, and StdErrFis > StdErrFst, Null alleles are likely to be the cause. - if the correlation between Fis and Fst is ~0 or mildly positive, and StdErrFis > StdErrFst, Wahlund may be the cause. - if the correlation between Fis and Fst is ~0, and StdErrFis ~ StdErrFst, selfing or sib mating could to be the cause. It is important to realise that these statistics only suggest a pattern (pointers). Their absence is not conclusive evidence of the absence of the problem, as their presence does not confirm the cause of the problem.

5. A table where the number of observed and expected significant HWE tests are reported by each population, indicating whether these are due to heterozygosity excess or deficiency. These can be used to have a clue of potential problems (e.g. deficiency might be due to a Wahlund effect, presence of null alleles or non-random sampling; excess might be due to sex linkage or different selection between sexes, demographic changes or small Ne. See Table 1 in Wapples 2015). The last two columns of the table generated by this function report chisquare values and their associated p-values. Chi-square is computed following Fisher’s procedure for a global test (Fisher 1970). This basically tests whether there is at least one test that is truly significant in the series of tests conducted (De Meeûs et al 2009).

Value

A list with the table with the summary of the HWE tests and (if stdErr=TRUE) a named vector with the StdErrFis and StdErrFst.

See Also

- gl.report.hwe

Other reporting functions: gl.report.bases(), gl.report.diversity(), gl.report.heterozygosity(), gl.report.parent.offspring(), gl.report.pa(), gl.report.sexlinked()

Examples

res <- gl.diagnostics.hwe(x = gl.filter.allna(platypus.gl[,1:50]), n.cores=1)
Arguments

- **x**: Output from function `gl.sim.WF.run` [required].
- **Ne**: Effective population size to use as input to compare theoretical expectations [required].
- **iteration**: Iteration number to analyse [default 1].
- **pop_he**: Population name in which the rate of loss of heterozygosity is going to be compared against theoretical expectations [default 1].
- **pops_fst**: Pair of populations in which FST is going to be compared against theoretical expectations [default c(1,2)].
- **plot_theme**: User specified theme [default theme_dartR()].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

Two plots are presented comparing the simulations against theoretical expectations:

1. Expected heterozygosity under neutrality (Crow & Kimura, 1970, p. 329) is calculated as:
   \[
   Het = He_0 \left(1 - \frac{1}{2Ne}\right)^t, 
   \]
   where Ne is effective population size, He0 is heterozygosity at generation 0 and t is the number of generations.

2. Expected FST under neutrality (Takahata, 1983) is calculated as:
   \[
   FST = \frac{1}{4Ne((n/(n-1)))^2+1}, 
   \]
   where Ne is effective populations size of each individual subpopulation, m is dispersal rate and n the number of subpopulations (always 2).

Value

Returns plots comparing simulations against theoretical expectations

**gl.dist.ind**

Calculates a distance matrix for individuals defined in a genlight object

---

**Description**

This script calculates various distances between individuals based on allele frequencies or presence-absence data.

**Usage**

```r
gl.dist.ind(
x, 
method = NULL, 
scale = FALSE, 
swap = FALSE, 
output = "dist", 
plot.out = TRUE, 
plot_theme = theme_dartR(), 
plot_colors = two_colors, 
save2tmp = FALSE, 
verbose = NULL
)
```

**Arguments**

- **x**: Name of the genlight containing the SNP genotypes or presence-absence data [required].
- **method**: Specify distance measure [SNP: Euclidean; P/A: Simple].
- **scale**: If TRUE, the distances are scaled to fall in the range [0,1] [default TRUE].
- **swap**: If TRUE and working with presence-absence data, then presence (no disrupting mutation) is scored as 0 and absence (presence of a disrupting mutation) is scored as 1 [default FALSE].
- **output**: Specify the format and class of the object to be returned, 'dist' for a object of class dist, 'matrix' for an object of class matrix [default "dist"].
- **plot.out**: If TRUE, display a histogram and a boxplot of the genetic distances [TRUE].
- **plot_theme**: User specified theme [default theme_dartR].
- **plot_colors**: Vector with two color names for the borders and fill [default two_colors].
- **save2tmp**: If TRUE, saves any ggplots to the session temporary directory [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
Details

The distance measure for SNP genotypes can be one of:

- Euclidean Distance [method = "Euclidean"]
- Scaled Euclidean Distance [method = "Euclidean", scale=TRUE]
- Simple Mismatch Distance [method = "Simple"]
- Absolute Mismatch Distance [method = "Absolute"]
- Czekanowski (Manhattan) Distance [method = "Manhattan"]

The distance measure for Sequence Tag Presence/Absence data (binary) can be one of:

- Euclidean Distance [method = "Euclidean"]
- Scaled Euclidean Distance [method = "Euclidean", scale=TRUE]
- Simple Matching Distance [method = "Simple"]
- Jaccard Distance [method = "Jaccard"]
- Bray-Curtis Distance [method = "Bray-Curtis"]

Refer to the dartR Technical Note on Distances in Genetics.

Value

An object of class `matrix` or `dist` giving distances between individuals

Author(s)

Author(s): Arthur Georges. Custodian: Arthur Georges – Post to #’ https://groups.google.com/d/forum/dartr

Examples

```r
D <- gl.dist.ind(testset.gl, method = 'euclidean', scale=TRUE)
D <- gl.dist.ind(testset.gl, method = 'manhattan')
D <- gl.dist.ind(testset.gs, method = 'Jaccard', swap=TRUE)
```

---

**gl.dist.pop**

Calculates a distance matrix for populations with SNP genotypes in a genlight object

Description

This script calculates various distances between populations based on allele frequencies (SNP genotypes) or frequency of presences in presence-absence data (Euclidean and Fixed-diff distances only).
Usage

```r
gl.dist.pop(
  x,  
  method = "euclidean", 
  plot.out = TRUE, 
  scale = FALSE, 
  output = "dist", 
  plot_theme = theme_dartR(), 
  plot_colors = two_colors,  
  save2tmp = FALSE, 
  verbose = NULL 
)
```

Arguments

- **x**: Name of the genlight containing the SNP genotypes [required].
- **method**: Specify distance measure [default euclidean].
- **plot.out**: If TRUE, display a histogram of the genetic distances, and a whisker plot [default TRUE].
- **scale**: If TRUE and method='Euclidean', the distance will be scaled to fall in the range [0,1] [default FALSE].
- **output**: Specify the format and class of the object to be returned, dist for a object of class dist, matrix for an object of class matrix [default “dist”].
- **plot_theme**: User specified theme [default theme_dartR()].
- **plot_colors**: Vector with two color names for the borders and fill [default two_colors].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

The distance measure can be one of ‘euclidean’, ‘fixed-diff’, ‘reynolds’, ‘nei’ and ‘chord’. Refer to the documentation of functions described in the the DartR Distance Analysis tutorial for algorithms and definitions.

Value

An object of class ’dist’ giving distances between populations

Author(s)

Examples

```r
# SNP genotypes
D <- gl.dist.pop(possums.gl[1:90,1:100], method='euclidean')
D <- gl.dist.pop(possums.gl[1:90,1:100], method='euclidean', scale=TRUE)
## Not run:
#D <- gl.dist.pop(possums.gl, method='nei')
#D <- gl.dist.pop(possums.gl, method='reynolds')
#D <- gl.dist.pop(possums.gl, method='chord')
#D <- gl.dist.pop(possums.gl, method='fixed-diff')
## End(Not run)

# Presence-Absence data [only 10 individuals due to speed]
D <- gl.dist.pop(testset.gs[1:10,], method='euclidean')
```

---

**gl.drop.ind**

*Removes specified individuals from a genlight {adegenet} object*

**Description**

The script, having deleted individuals, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using gl.filter.monomorphs.r). The script also optionally recalculates statistics made redundant by the deletion of individuals from the dataset.

The script returns a genlight object with the individuals deleted and, optionally, the recalculated locus metadata.

**Usage**

```r
gl.drop.ind(x, ind.list, recalc = FALSE, mono.rm = FALSE, verbose = NULL)
```

**Arguments**

- `x`: Name of the genlight object containing SNP genotypes [required].
- `ind.list`: A list of individuals to be removed [required].
- `recalc`: Recalculate the locus metadata statistics [default FALSE].
- `mono.rm`: Remove monomorphic loci [default FALSE].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Value**

A genlight object with the reduced data

**Author(s)**

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr
gl.drop.loc

Removes specified loci from a genlight {adegenet} object

Description
The script returns a genlight object with specified loci deleted.

Usage

```r
gl.drop.loc(x, loc.list = NULL, first = NULL, last = NULL, verbose = NULL)
```

Arguments

- `x` Name of the genlight object containing SNP genotypes or presence/absence data [required].
- `loc.list` A list of loci to be deleted [required, if loc.range not specified].
- `first` First of a range of loci to be deleted [required, if loc.list not specified].
- `last` Last of a range of loci to be deleted [if not specified, last locus in the dataset].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value
A genlight object with the reduced data.

Author(s)
Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

See Also

- `gl.keep.ind` to keep rather than drop specified individuals

Examples

```r
# SNP data
gl2 <- gl.drop.ind(testset.gl,
                   ind.list=c('AA019073','AA004859'))

# Tag P/A data
gs2 <- gl.drop.ind(testset.gs,
                   ind.list=c('AA020656','AA19077','AA004859'),
                   mono.rm=TRUE, recalc=TRUE)
```

`gl.keep.loc` to keep rather than drop specified loci

Examples

```r
# SNP data
gl2 <- gl.drop.pop(testset.gl, loc.list=c('100051468|42-A/T', '100049816-51-A/G'), verbose=3)
# Tag P/A data
gs2 <- gl.drop.pop(testset.gs, loc.list=c('20134188', '19249144'), verbose=3)
```

---

**gl.drop.pop**

Removes specified populations from a genlight object

### Description

Individuals are assigned to populations based on the specimen metadata file (csv) used with `gl.read.dart`. The script, having deleted populations, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using `gl.filter.monomorphs.r`). The script also optionally recalculates statistics made redundant by the deletion of individuals from the dataset.

The script returns a genlight object with the new population assignments and the recalculated locus metadata.

### Usage

```r
gl.drop.pop(
  x,  
  pop.list,  
  as.pop = NULL,  
  recalc = FALSE,  
  mono.rm = FALSE,  
  verbose = NULL  
)
```

### Arguments

- **x** Name of the genlight object containing SNP genotypes or Tag P/A data (Silico-DArT) [required].
- **pop.list** A list of populations to be removed [required].
- **as.pop** Temporarily assign another metric to represent population for the purposes of deletions [default NULL].
- **recalc** Recalculate the locus metadata statistics [default FALSE].
- **mono.rm** Remove monomorphic loci [default FALSE].
- **verbose** Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`].
**Value**

A genlight object with the reduced data

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**See Also**

- `gl.keep.pop` to keep rather than drop specified populations

**Examples**

```r
# SNP data
gl2 <- gl.drop.pop(testset.gl, pop.list = c("EmsubRopeMata", "EmvicVictJasp"), verbose = 3)
gl2 <- gl.drop.pop(testset.gl, pop.list = c("EmsubRopeMata", "EmvicVictJasp"), mono.rm = TRUE, recalc = TRUE)
gl2 <- gl.drop.pop(testset.gl, pop.list = c("Male", "Unknown"), as.pop = "sex")

# Tag P/A data
gs2 <- gl.drop.pop(testset.gs, pop.list = c("EmsubRopeMata", "EmvicVictJasp"))
```

---

**Description**

A script to edit individual names in a genlight object, or to create a reassignment table taking the individual labels from a genlight object, or to edit existing individual labels in an existing recode_ind file.

**Usage**

```r
gl.edit.recode.ind(
  x,
  out.recode.file = NULL,
  outpath = tempdir(),
  recalc = FALSE,
  mono.rm = FALSE,
  verbose = NULL
)
```
Arguments

- **x**: Name of the genlight object for which individuals are to be relabelled [required].
- **out.recode.file**: Name of the file to output the new individual labels [optional].
- **outpath**: Path where to save the output file [default tempdir(), mandated by CRAN].
- **recalc**: Recalculate the locus metadata statistics [default TRUE].
- **mono.rm**: Remove monomorphic loci [default TRUE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

Renaming individuals may be required when there have been errors in labelling arising in the process from sample to DArT files. There may be occasions where renaming individuals is required for preparation of figures. Caution needs to be exercised because of the potential for breaking the ‘chain of evidence’ between the samples themselves and the analyses. Recoding individuals can also be done with a recode table (csv).

This script will input an existing recode table for editing and optionally save it as a new table, or if the name of an input table is not supplied, will generate a table using the individual labels in the parent genlight object.

The script, having deleted individuals, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using gl.filter.monomorphs.r). The script also optionally recalculates statistics made redundant by the deletion of individuals from the dataset.

Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.

The script returns a genlight object with the new individual labels and the recalculated locus metadata.

Value

An object of class ('genlight') with the revised individual labels.

Examples

```r
## Not run:
gl <- gl.edit.recode.ind(testset.gl)
gl <- gl.edit.recode.ind(testset.gl, out.recode.file='ind.recode.table.csv')
## End(Not run)
```
Description

A script to edit population assignments in a genlight object, or to create a reassignment table taking the population assignments from a genlight object, or to edit existing population assignments in a pop.recode.table.

Usage

```r
gl.edit.recode.pop(
  x,
  pop.recode = NULL,
  out.recode.file = NULL,
  outpath = tempdir(),
  recalc = FALSE,
  mono.rm = FALSE,
  verbose = NULL
)
```

Arguments

- `x`: Name of the genlight object for which populations are to be reassigned [required].
- `pop.recode`: Path to recode file [default NULL].
- `out.recode.file`: Name of the file to output the new individual labels [default NULL].
- `outpath`: Path where to save the output file [default tempdir(), mandated by CRAN].
- `recalc`: Recalculate the locus metadata statistics if any individuals are deleted [default TRUE].
- `mono.rm`: Remove monomorphic loci [default TRUE].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

Genlight objects assign specimens to populations based on information in the ind.metadata file provided when the genlight object is first generated. Often one wishes to subset the data by deleting populations or to amalgamate populations. This can be done with a pop.recode table with two columns. The first column is the population assignment in the genlight object, the second column provides the new assignment.

This script will input an existing reassignment table for editing and optionally save it as a new table, or if the name of an input table is not supplied, will generate a table using the population assignments in the parent genlight object.
The script, having deleted populations, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using \texttt{gl.filter.monomorphs.r}). The script also optionally recalculates statistics made redundant by the deletion of individuals from the dataset.

Use \texttt{outpath=getwd()} or \texttt{outpath=’.’} when calling this function to direct output files to your working directory.

The script returns a genlight object with the new population assignments and the recalculated locus metadata.

Value

An object of class (’genlight’) with the revised population assignments

  gl.evanno
\end{verbatim}

\textit{Creates an Evanno plot from a STRUCTURE run object}

Description

This function takes a genlight object and runs a STRUCTURE analysis based on functions from \texttt{strataG}

Usage

\texttt{gl.evanno(sr, plot.out = TRUE)}

Arguments

\begin{itemize}
  \item \texttt{sr} structure run object from \texttt{gl.run.structure} [required].
  \item \texttt{plot.out} \texttt{TRUE}: all four plots are shown. \texttt{FALSE}: all four plots are returned as a ggplot but not shown [default \texttt{TRUE}].
\end{itemize}
Details

The function is basically a convenient wrapper around the beautiful strataG function evanno (Archer et al. 2016). For a detailed description please refer to this package (see references below).

Value

An Evanno plot is created and a list of all four plots is returned.

`gl.fdsim` *Estimates the rate of false positives in a fixed difference analysis*
Description
This function takes two populations and generates allele frequency profiles for them. It then samples
an allele frequency for each, at random, and estimates a sampling distribution for those two allele
frequencies. Drawing two samples from those sampling distributions, it calculates whether or not
they represent a fixed difference. This is applied to all loci, and the number of fixed differences so
generated are counted, as an expectation. The script distinguished between true fixed differences
(with a tolerance of delta), and false positives. The simulation is repeated a given number of times
(default=1000) to provide an expectation of the number of false positives, given the observed allele
frequency profiles and the sample sizes. The probability of the observed count of fixed differences
is greater than the expected number of false positives is calculated.

Usage
```r
gl.fdsim(
  x,
  poppair,
  obs = NULL,
  sympatric = FALSE,
  reps = 1000,
  delta = 0.02,
  verbose = NULL
)
```

Arguments
- `x` Name of the genlight containing the SNP genotypes [required].
- `poppair` Labels of two populations for comparison in the form c(popA, popB) [required].
- `obs` Observed number of fixed differences between the two populations [default NULL].
- `sympatric` If TRUE, the two populations are sympatric, if FALSE then allopatric [default FALSE].
- `reps` Number of replications to undertake in the simulation [default 1000].
- `delta` The threshold value for the minor allele frequency to regard the difference be-
tween two populations to be fixed [default 0.02].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress
and results summary; 5, full report [default 2].

Value
A list containing the following square matrices [[1]] observed fixed differences; [[2]] mean expected
number of false positives for each comparison; [[3]] standard deviation of the no. of false positives
for each comparison; [[4]] probability the observed fixed differences arose by chance for each
comparison.

fd <- gl.fdsm(testset.gl, poppair=c('EmsubRopeMata', 'EmmacBurnBara'), sympatric=TRUE, verbose=3)
```

---

**gl.filter.allna**

Filters loci that are all NA across individuals and/or populations with all NA across loci

---

**Description**

This script deletes individuals or populations with all calls missing (NA), from a genlight object. A DArT dataset will not have loci for which the calls are scored all as missing (NA) for a particular individual, but such loci can arise rarely when populations or individuals are deleted. Similarly, a DArT dataset will not have individuals for which the calls are scored all as missing (NA) across all loci, but such individuals may sneak in to the dataset when loci are deleted. Retaining individual or loci with all NAs can cause issues for several functions.

Also, on occasion an analysis will require that there are some loci scored in each population. Setting by.pop=TRUE will result in removal of loci when they are all missing in any one population.

Note that loci that are missing for all individuals in a population are not imputed with method 'frequency' or 'HW'. Consider using the function `gl.filter.allna` with by.pop=TRUE.

**Usage**

```r
gl.filter.allna(x, by.pop = FALSE, recal = FALSE, verbose = NULL)
```

**Arguments**

- **x**: Name of the input genlight object [required].
- **by.pop**: If TRUE, loci that are all missing in any one population are deleted [default FALSE]
- **recalc**: Recalculate the locus metadata statistics if any individuals are deleted in the filtering [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

**Value**

A genlight object having removed individuals that are scored NA across all loci, or loci that are scored NA across all individuals.

**Author(s)**

Author(s): Arthur Georges. Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr
gl.filter.callrate

Filters loci or specimens in a genlight \{adegenet\} object based on call rate

Description

SNP datasets generated by DArT have missing values primarily arising from failure to call a SNP because of a mutation at one or both of the restriction enzyme recognition sites. The script gl.filter.callrate() will filter out the loci with call rates below a specified threshold.

Tag Presence/Absence datasets (SilicoDArT) have missing values where it is not possible to determine reliably if there the sequence tag can be called at a particular locus.

Usage

```r
gl.filter.callrate(
  x,
  method = "loc",
  threshold = 0.95,
  mono.rm = FALSE,
  recalc = FALSE,
  recursive = FALSE,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  bins = 25,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- `x` Name of the genlight object containing the SNP data, or the genind object containing the SilicoDArT data [required].
method  Use method='loc' to specify that loci are to be filtered, 'ind' to specify that specimens are to be filtered, 'pop' to remove loci that fail to meet the specified threshold in any one population [default 'loc'].

threshold  Threshold value below which loci will be removed [default 0.95].

mono.rm  Remove monomorphic loci after analysis is complete [default FALSE].

recalc  Recalculate the locus metadata statistics if any individuals are deleted in the filtering [default FALSE].

recursive  Repeatedly filter individuals on call rate, each time removing monomorphic loci. Only applies if method='ind' and mono.rm=TRUE [default FALSE].

plot.out  Specify if histograms of call rate, before and after, are to be produced [default TRUE].

plot_theme  User specified theme for the plot [default theme_dartR()].

plot_colors  List of two color names for the borders and fill of the plots [default two_colors].

bins  Number of bins to display in histograms [default 25].

save2tmp  If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].

verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

Because this filter operates on call rate, this function recalculates Call Rate, if necessary, before filtering. If individuals are removed using method='ind', then the call rate stored in the genlight object is, optionally, recalculated after filtering.

Note that when filtering individuals on call rate, the initial call rate is calculated and compared against the threshold. After filtering, if mono.rm=TRUE, the removal of monomorphic loci will alter the call rates. Some individuals with a call rate initially greater than the nominated threshold, and so retained, may come to have a call rate lower than the threshold. If this is a problem, repeated iterations of this function will resolve the issue. This is done by setting mono.rm=TRUE and recursive=TRUE, or it can be done manually.

Callrate is summarized by locus or by individual to allow sensible decisions on thresholds for filtering taking into consideration consequential loss of data. The summary is in the form of a tabulation and plots.

Plot themes can be obtained from

- [https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/](https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/)

Resultant ggplot(s) and the tabulation(s) are saved to the session’s temporary directory.

Value

The reduced genlight or genind object, plus a summary
gl.filter.hamming

Filters loci based on pairwise Hamming distance between sequence tags

Description

Hamming distance is calculated as the number of base differences between two sequences which can be expressed as a count or a proportion. Typically, it is calculated between two sequences of equal length. In the context of DArT trimmed sequences, which differ in length but which are anchored to the left by the restriction enzyme recognition sequence, it is sensible to compare the two trimmed sequences starting from immediately after the common recognition sequence and terminating at the last base of the shorter sequence.

Usage

```r
gl.filter.hamming(
  x,
  threshold = 0.2,
  rs = 5,
  taglength = 69,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  pb = FALSE,
  save2tmp = FALSE,
  verbose = NULL
)
```

Examples

```r
# SNP data
result <- gl.filter.callrate(testset.gl[1:10], method='loc', threshold=0.8, verbose=3)
result <- gl.filter.callrate(testset.gl[1:10], method='ind', threshold=0.8, verbose=3)
result <- gl.filter.callrate(testset.gl[1:10], method='pop', threshold=0.8, verbose=3)

# Tag P/A data
result <- gl.filter.callrate(testset.gs[1:10], method='loc', threshold=0.95, verbose=3)
result <- gl.filter.callrate(testset.gs[1:10], method='ind', threshold=0.8, verbose=3)
result <- gl.filter.callrate(testset.gs[1:10], method='pop', threshold=0.8, verbose=3)
```
Arguments

- **x**: Name of the genlight object containing the SNP data [required].
- **threshold**: A threshold Hamming distance for filtering loci [default threshold 0.2].
- **rs**: Number of bases in the restriction enzyme recognition sequence [default 5].
- **taglength**: Typical length of the sequence tags [default 69].
- **plot.out**: Specify if plot is to be produced [default TRUE].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: List of two color names for the borders and fill of the plots [default two_colors].
- **pb**: Switch to output progress bar [default FALSE].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

Hamming distance can be computed by exploiting the fact that the dot product of two binary vectors x and (1-y) counts the corresponding elements that are different between x and y. This approach can also be used for vectors that contain more than two possible values at each position (e.g. A, C, T or G).

If a pair of DNA sequences are of differing length, the longer is truncated.

The algorithm is that of Johann de Jong [https://johanndejong.wordpress.com/2015/10/02/faster-hamming-distance-in-r-2/](https://johanndejong.wordpress.com/2015/10/02/faster-hamming-distance-in-r-2/) as implemented in `utils.hamming`.

Only one of two loci are retained if their Hamming distance is less that a specified percentage. 5 base differences out of 100 bases is a 20

Value

A genlight object filtered on Hamming distance.

gl.filter.heterozygosity

*Filters individuals with average heterozygosity greater than a specified upper threshold or less than a specified lower threshold*

Description

Calculates the observed heterozygosity for each individual in a genlight object and filters individuals based on specified threshold values. Use gl.report.heterozygosity to determine the appropriate thresholds.

Usage

```r
gl.filter.heterozygosity(x, t.upper = 0.7, t.lower = 0, verbose = NULL)
```

Arguments

- `x`: A genlight object containing the SNP genotypes [required].
- `t.upper`: Filter individuals > the threshold [default 0.7].
- `t.lower`: Filter individuals < the threshold [default 0].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

The filtered genlight object.

Author(s)

Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

Examples

```r
result <- gl.filter.heterozygosity(testset.gl,t.upper=0.06,verbose=3)
tmp <- gl.report.heterozygosity(result,method='ind')
```
gl.filter.hwe

**Filters loci that show significant departure from Hardy-Weinberg Equilibrium**

**Description**

This function filters out loci showing significant departure from H-W proportions based on observed frequencies of reference homozygotes, heterozygotes and alternate homozygotes. Loci are filtered out if they show HWE departure in any one population.

**Usage**

```r
gl.filter.hwe(
  x,
  subset = "each",
  n.pop.threshold = 1,
  method_sig = "Exact",
  multi_comp = FALSE,
  multi_comp_method = "BY",
  alpha_val = 0.05,
  pvalue_type = "midp",
  cc_val = 0.5,
  min_sample_size = 5,
  verbose = NULL
)
```

**Arguments**

- **x** Name of the genlight object containing the SNP data [required].
- **subset** Way to group individuals to perform H-W tests. Either a vector with population names, 'each', 'all' (see details) [default 'each'].
- **n.pop.threshold** The minimum number of populations where the same locus has to be out of hwe to be removed [default 1]
- **method_sig** Method for determining statistical significance: 'ChiSquare' or 'Exact' [default 'Exact'].
- **multi_comp** Whether to adjust p-values for multiple comparisons [default FALSE].
- **multi_comp_method** Method to adjust p-values for multiple comparisons: 'holm', 'hochberg', 'hommel', 'bonferroni', 'BH', 'BY', 'fdr' (see details) [default 'fdr'].
- **alpha_val** Level of significance for testing [default 0.05].
- **pvalue_type** Type of p-value to be used in the Exact method. Either 'dost','selome','midp' (see details) [default 'midp'].
- **cc_val** The continuity correction applied to the ChiSquare test [default 0.5].
min_sample_size  Minimum number of individuals per population in which perform H-W tests [default 5].

verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

There are several factors that can cause deviations from Hardy-Weinberg proportions including: mutation, finite population size, selection, population structure, age structure, assortative mating, sex linkage, nonrandom sampling and genotyping errors. Therefore, testing for Hardy-Weinberg proportions should be a process that involves a careful evaluation of the results, a good place to start is Waples (2015).

Note that tests for H-W proportions are only valid if there is no population substructure (assuming random mating) and have sufficient power only when there is sufficient sample size (n individuals > 15).

Populations can be defined in three ways:

- Merging all populations in the dataset using subset = 'all'.
- Within each population separately using: subset = 'each'.
- Within selected populations using for example: subset = c('pop1','pop2').

Two different statistical methods to test for deviations from Hardy Weinberg proportions:

- The classical chi-square test (method_sig='ChiSquare') based on the function HWChisq of the R package HardyWeinberg. By default a continuity correction is applied (cc_val=0.5). The continuity correction can be turned off (by specifying cc_val=0), for example in cases of extreme allele frequencies in which the continuity correction can lead to excessive type 1 error rates.
- The exact test (method_sig='Exact') based on the exact calculations contained in the function HWExactStats of the R package HardyWeinberg, and described in Wigginton et al. (2005). The exact test is recommended in most cases (Wigginton et al., 2005). Three different methods to estimate p-values (pvalue_type) in the Exact test can be used:
  - 'dost' p-value is computed as twice the tail area of a one-sided test.
  - 'selome' p-value is computed as the sum of the probabilities of all samples less or equally likely as the current sample.
  - 'midp', p-value is computed as half the probability of the current sample + the probabilities of all samples that are more extreme.

The standard exact p-value is overly conservative, in particular for small minor allele frequencies. The mid p-value ameliorates this problem by bringing the rejection rate closer to the nominal level, at the price of occasionally exceeding the nominal level (Graffelman & Moreno, 2013).

Correction for multiple tests can be applied using the following methods based on the function p.adjust:
• ‘holm’ is also known as the sequential Bonferroni technique (Rice, 1989). This method has a greater statistical power than the standard Bonferroni test, however this method becomes very stringent when many tests are performed and many real deviations from the null hypothesis can go undetected (Waples, 2015).
• ‘hommel’ based on Hommel, 1988. This method is more powerful than Hochberg’s, but the difference is usually small.
• ‘bonferroni’ in which p-values are multiplied by the number of tests. This method is very stringent and therefore has reduced power to detect multiple departures from the null hypothesis.
• ‘BH’ based on Benjamini & Hochberg, 1995.
• ‘BY’ based on Benjamini & Yekutieli, 2001.

The first four methods are designed to give strong control of the family-wise error rate. The last two methods control the false discovery rate (FDR), the expected proportion of false discoveries among the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others, especially when number of tests is large. The number of tests on which the adjustment for multiple comparisons is the number of populations times the number of loci.

From v2.1 gl.filter.hwe takes the argument n.pop.threshold. if n.pop.threshold > 1 loci will be removed only if they are concurrently significant (after adjustment if applied) out of hwe in >= n.pop.threshold > 1.

Value
A genlight object with the loci departing significantly from H-W proportions removed.

**gl.filter.locmetrics**

*Filters loci on the basis of numeric information stored in other$loc.metrics in a genlight [adegenet] object*

**Description**

This script uses any field with numeric values stored in $other$loc.metrics to filter loci. The loci to keep can be within the upper and lower thresholds (‘within’) or outside of the upper and lower thresholds (‘outside’).

The fields that are included in dartR, and a short description, are found below. Optionally, the user can also set his/her own filter by adding a vector into $other$loc.metrics as shown in the example.

1. SnpPosition - position (zero is position 1) in the sequence tag of the defined SNP variant base.
2. CallRate - proportion of samples for which the genotype call is non-missing (that is, not ‘-’).
3. OneRatioRef - proportion of samples for which the genotype score is 0.
4. OneRatioSnp - proportion of samples for which the genotype score is 2.
5. FreqHomRef - proportion of samples homozygous for the Reference allele.
6. FreqHomSnp - proportion of samples homozygous for the Alternate (SNP) allele.
7. FreqHets - proportion of samples which score as heterozygous, that is, scored as 1.
8. PICRef - polymorphism information content (PIC) for the Reference allele.
9. PICSnp - polymorphism information content (PIC) for the SNP.
10. AvgPIC - average of the polymorphism information content (PIC) of the Reference and SNP alleles.
11. AvgCountRef - sum of the tag read counts for all samples, divided by the number of samples with non-zero tag read counts, for the Reference allele row.
12. AvgCountSnp - sum of the tag read counts for all samples, divided by the number of samples with non-zero tag read counts, for the Alternate (SNP) allele row.
13. RepAvg - proportion of technical replicate assay pairs for which the marker score is consistent.
Usage

```r
gl.filter.locmetric(x, metric, upper, lower, keep = "within", verbose = NULL)
```

Arguments

- `x`: Name of the genlight object containing the SNP data [required].
- `metric`: Name of the metric to be used for filtering [required].
- `upper`: Filter upper threshold [required].
- `lower`: Filter lower threshold [required].
- `keep`: Whether keep loci within of upper and lower thresholds or keep loci outside of upper and lower thresholds [within].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

The reduced genlight dataset.

Author(s)

Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

Examples

```r
# adding dummy data
test <- testset.gl
test$other$loc.metrics$test <- 1:nLoc(test)
result <- gl.filter.locmetric(x=test, metric='test', upper=255, lower=200, keep='within', verbose=3)
```

Description

This script calculates the minor allele frequency for each locus and updates the locus metadata for FreqHomRef, FreqHomSnp, FreqHets and MAF (if it exists). It then uses the updated metadata for MAF to filter loci.
Usage

```r
gl.filter.maf(
  x,
  threshold = 0.01,
  by.pop = FALSE,
  pop.limit = ceiling(nPop(x)/2),
  ind.limit = 10,
  recalc = FALSE,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors_pop = discrete_palette,
  plot_colors_all = two_colors,
  bins = 25,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- **x**: Name of the genlight object containing the SNP data [required].
- **threshold**: Threshold MAF – loci with a MAF less than the threshold will be removed [default 0.01]. If a value > 1 is provided it will be interpreted as MAC (i.e. the minimum number of times an allele needs to be observed).
- **by.pop**: Whether MAF should be calculated by population [default FALSE].
- **pop.limit**: Minimum number of populations in which MAF should be less than the threshold for a locus to be filtered out. Only used if by.pop=TRUE. The default value is half of the populations [default ceiling(nPop(x)/2)].
- **ind.limit**: Minimum number of individuals that a population should contain to calculate MAF. Only used if by.pop=TRUE [default 10].
- **recalc**: Recalculate the locus metadata statistics if any individuals are deleted in the filtering [default FALSE].
- **plot.out**: Specify if histograms of call rate, before and after, are to be produced [default TRUE].
- **plot_theme**: User specified theme for the plot [default theme_dartR()].
- **plot_colors_pop**: A color palette for population plots [default discrete_palette].
- **plot_colors_all**: List of two color names for the borders and fill of the overall plot [default two_colors].
- **bins**: Number of bins to display in histograms [default 25].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].
**Details**

Careful consideration needs to be given to the settings to be used for this function. When the filter is applied globally (i.e. `by.pop=FALSE`) but the data include multiple population, there is the risk to remove markers because the allele frequencies is low (at global level) but the allele frequencies for the same markers may be high within some of the populations (especially if the per-population sample size is small). Similarly, not always it is a sensible choice to run this function using `by.pop=TRUE` because allele that are rare in a population may be very common in other, but the (possible) allele frequencies will depend on the sample size within each population. Where the purpose of filtering for MAF is to remove possible spurious alleles (i.e. sequencing errors), it is perhaps better to filter based on the number of times an allele is observed (MAC, Minimum Allele Count), under the assumption that if an allele is observed >MAC, it is fairly rare to be an error. **From v2.1** The threshold can take values > 1. In this case, these are interpreted as a threshold for MAC.

**Value**

The reduced genlight dataset

**Author(s)**

Custodian: Luis Mijangos – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**Examples**

```r
result <- gl.filter.monomorphs(testset.gl)
result <- gl.filter.maf(result, threshold=0.05, verbose=3)
```

---

**gl.filter.monomorphs**  
*Filters monomorphic loci, including those with all NAs*

**Description**

This script deletes monomorphic loci from a genlight {adegenet} object

A DArT dataset will not have monomorphic loci, but they can arise, along with loci that are scored all NA, when populations or individuals are deleted.

Retaining monomorphic loci unnecessarily increases the size of the dataset and will affect some calculations.

Note that for SNP data, NAs likely represent null alleles; in tag presence/absence data, NAs represent missing values (presence/absence could not be reliably scored)

**Usage**

```r
gl.filter.monomorphs(x, verbose = NULL)
```
Arguments

- **x** Name of the input genlight object [required].
- **verbose** Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using `gl.set.verbosity`].

Value

A genlight object with monomorphic (and all NA) loci removed.

Author(s)

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

See Also

Other filters and filter reports:  
- `gl.filter.allna()`, `gl.filter.rdepth()`, `gl.filter.reproducibility()`,  
- `gl.filter.secondaries()`, `gl.report.callrate()`, `gl.report.hamming()`, `gl.report.locmetric()`,  
- `gl.report.monomorphs()`, `gl.report.rdepth()`, `gl.report.reproducibility()`, `gl.report.taglength()`

Examples

```r
# SNP data
result <- gl.filter.monomorphs(testset.gl, verbose=3)
# Tag P/A data
result <- gl.filter.monomorphs(testset.gs, verbose=3)
```

Description

This function checks the position of the SNP within the trimmed sequence tag and identifies those for which the SNP position is outside the trimmed sequence tag. This can happen, rarely, when the sequence containing the SNP resembles the adaptor.

The SNP genotype can still be used in most analyses, but functions like `gl2fasta()` will present challenges if the SNP has been trimmed from the sequence tag.

Not fatal, but should apply this filter before `gl.filter.secondaries`, for obvious reasons.

Usage

```r
gl.filter.overshoot(x, save2tmp = FALSE, verbose = NULL)
```
gl.filter.pa

Arguments

x Name of the genlight object [required].
save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

A new genlight object with the recalcitrant loci deleted

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

result <- gl.filter.overshoot(testset.gl, verbose=3)

gl.filter.pa

Filters loci that contain private (and fixed alleles) between two populations

Description

This script is meant to be used prior to gl.nhybrids to maximise the information content of the SNPs used to identify hybrids (currently newhybrids does allow only 200 SNPs). The idea is to use first all loci that have fixed alleles between the potential source populations and then ‘fill up’ to 200 loci using loci that have private alleles between those. The functions filters for those loci (if invers is set to TRUE, the opposite is returned (all loci that are not fixed and have no private alleles - not sure why yet, but maybe useful.)

Usage

gl.filter.pa(x, pop1, pop2, invers = FALSE, verbose = NULL)

Arguments

x Name of the genlight object containing the SNP data [required].
pop1 Name of the first parental population (in quotes) [required].
pop2 Name of the second parental population (in quotes) [required].
invers Switch to filter for all loci that have no private alleles and are not fixed [FALSE].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].
Value

The reduced genlight dataset, containing now only fixed and private alleles.

Author(s)

Authors: Bernd Gruber & Ella Kelly (University of Melbourne); Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

Examples

result <- gl.filter.pa(testset.gl, pop1=pop(testset.gl)[1], pop2=pop(testset.gl)[2], verbose=3)

---

**gl.filter.parent.offspring**

*Filters putative parent offspring within a population*

Description

This script removes individuals suspected of being related as parent-offspring, using the output of the function `gl.report.parent.offspring`, which examines the frequency of pedigree inconsistent loci, that is, those loci that are homozygotes in the parent for the reference allele, and homozygous in the offspring for the alternate allele. This condition is not consistent with any pedigree, regardless of the (unknown) genotype of the other parent. The pedigree inconsistent loci are counted as an indication of whether or not it is reasonable to propose the two individuals are in a parent-offspring relationship.

Usage

```r
gl.filter.parent.offspring(
  x,
  min.rdepth = 12,
  min.reproducibility = 1,
  range = 1.5,
  method = "best",
  rm.monomorphs = FALSE,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- `x` Name of the genlight object containing the SNP genotypes [required].
- `min.rdepth` Minimum read depth to include in analysis [default 12].
min.reproducibility
   Minimum reproducibility to include in analysis [default 1].
range
   Specifies the range to extend beyond the interquartile range for delimiting outliers [default 1.5 interquartile ranges].
method
   Method of selecting the individual to retain from each pair of parent offspring relationship, 'best' (based on CallRate) or 'random' [default 'best'].
rm.monomorphs
   If TRUE, remove monomorphic loci after filtering individuals [default FALSE].
plot.out
   Specify if plot is to be produced [default TRUE].
plot_theme
   Theme for the plot. See Details for options [default theme_dartR()].
plot_colors
   List of two color names for the borders and fill of the plots [default two_colors].
save2tmp
   If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose
   Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

If two individuals are in a parent offspring relationship, the true number of pedigree inconsistent loci should be zero, but SNP calling is not infallible. Some loci will be miss-called. The problem thus becomes one of determining if the two focal individuals have a count of pedigree inconsistent loci less than would be expected of typical unrelated individuals. There are some quite sophisticated software packages available to formally apply likelihoods to the decision, but we use a simple outlier comparison.

To reduce the frequency of miss-calls, and so emphasize the difference between true parent-offspring pairs and unrelated pairs, the data can be filtered on read depth. Typically minimum read depth is set to 5x, but you can examine the distribution of read depths with the function gl.report.rdepth and push this up with an acceptable loss of loci. 12x might be a good minimum for this particular analysis. It is sensible also to push the minimum reproducibility up to 1, if that does not result in an unacceptable loss of loci. Reproducibility is stored in the slot @other$loc.metrics$RepAvg and is defined as the proportion of technical replicate assay pairs for which the marker score is consistent. You can examine the distribution of reproducibility with the function gl.report.reproducibility.

Note that the null expectation is not well defined, and the power reduced, if the population from which the putative parent-offspring pairs are drawn contains many sibs. Note also that if an individual has been genotyped twice in the dataset, the replicate pair will be assessed by this script as being in a parent-offspring relationship.

You should run gl.report.parent.offspring before filtering. Use this report to decide min.rdepth and min.reproducibility and assess impact on your dataset.

Note that if your dataset does not contain RepAvg or rdepth among the locus metrics, the filters for reproducibility and read depth are no used.

Function’s output

Plots and table are saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

out <- gl.filter.parent.offspring(testset.gl[1:10])
```

---

**gl.filter.rdepth**  
*Filters loci based on counts of sequence tags scored at a locus (read depth)*

**Description**

SNP datasets generated by DArT report AvgCountRef and AvgCountSnp as counts of sequence tags for the reference and alternate alleles respectively. These can be used to back calculate Read Depth. Fragment presence/absence datasets as provided by DArT (SilicoDArT) provide Average Read Depth and Standard Deviation of Read Depth as standard columns in their report.

Filtering on Read Depth using the companion script gl.filter.rdepth can be on the basis of loci with exceptionally low counts, or loci with exceptionally high counts.

**Usage**

```r
gl.filter.rdepth(  
  x,  
  lower = 5,  
  upper = 50,  
  plot.out = TRUE,  
  plot_theme = theme_dartR(),  
  plot_colors = two_colors,  
  save2tmp = FALSE,  
  verbose = NULL  
)
```
Arguments

- **x**: Name of the genlight object containing the SNP or tag presence/absence data [required].
- **lower**: Lower threshold value below which loci will be removed [default 5].
- **upper**: Upper threshold value above which loci will be removed [default 50].
- **plot.out**: Specify if plot is to be produced [default TRUE].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: List of two color names for the borders and fill of the plots [default two_colors].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

For examples of themes, see:

- [https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/](https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/)

Value

Returns a genlight object retaining loci with a Read Depth in the range specified by the lower and upper threshold.

Author(s)

Custodian: Arthur Georges (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

Examples

```r
# SNP data
result <- gl.filter.rdepth(testset.gl, lower=8, upper=50, verbose=3)
# Tag P/A data
result <- gl.filter.rdepth(testset.gs, lower=8, upper=50, verbose=3)
```
**gl.filter.reproducibility**

*Filters loci in a genlight* adegenet* object based on average repeatability of alleles at a locus*

---

**Description**

SNP datasets generated by DArT have an index, RepAvg, generated by reproducing the data independently for 30 of alleles that give a repeatable result, averaged over both alleles for each locus. SilicoDArT datasets generated by DArT have a similar index, Reproducibility. For these fragment presence/absence data, repeatability is the percentage of scores that are repeated in the technical replicate dataset.

**Usage**

```r
gl.filter.reproducibility(
  x,
  threshold = 0.99,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data [required].
- `threshold` Threshold value below which loci will be removed [default 0.99].
- `plot.out` If TRUE, displays a plots of the distribution of reproducibility values before and after filtering [default TRUE].
- `plot_theme` Theme for the plot [default theme_dartR()].
- `plot_colors` List of two color names for the borders and fill of the plots [default two_colors].
- `save2tmp` If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

**Value**

Returns a genlight object retaining loci with repeatability (Repavg or Reproducibility) greater than the specified threshold.

result <- gl.filter.secondaries(testset.gs, threshold=0.99)

---

See gl.filter.secondaries

Filters loci that represent secondary SNPs in a genlight object

Description

SNP datasets generated by DArT include fragments with more than one SNP and record them sepa-
rately with the same CloneID (=AlleleID). These multiple SNP loci within a fragment (secondaries) are likely to be linked, and so you may wish to remove secondaries.

This script filters out all but the first sequence tag with the same CloneID after ordering the genlight object on based on repeatability, avgPIC in that order (method='best') or at random (method='random').

The filter has not been implemented for tag presence/absence data.

Usage

gl.filter.secondaries(x, method = "random", verbose = NULL)

Arguments

x

Name of the genlight object containing the SNP data [required].

method

Method of selecting SNP locus to retain, 'best' or 'random' [default 'random'].

verbose

Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

The genlight object, with the secondary SNP loci removed.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

gl.report.secondaries(testset.gl)
result <- gl.filter.secondaries(testset.gl)
```

---

**gl.filter.sexlinked**  
*Filters loci that are sex linked*

### Description

Alleles unique to the Y or W chromosome and monomorphic on the X chromosomes will appear in the SNP dataset as genotypes that are heterozygotic in all individuals of the heterogametic sex and homozygous in all individuals of the homogametic sex. This function keeps or drops loci with alleles that behave in this way, as putative sex specific SNP markers.

### Usage

```r
gl.filter.sexlinked(
  x,
  sex = NULL,
  filter = NULL,
  read.depth = 0,
  t.het = 0.1,
  t.hom = 0.1,
  t.pres = 0.1,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = three_colors,
  verbose = NULL
)
```

### Arguments

- **x**  
  Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].
- **sex**  
  Factor that defines the sex of individuals. See explanation in details [default NULL].
- **filter**  
  Either 'keep' to keep sex linked markers only or 'drop' to drop sex linked markers [required].
- **read.depth**  
  Additional filter option to keep only loci above a certain read.depth. Default to 0, which means read.depth is not taken into account [default 0].
gl.filter.sexlinked

### Parameters

- **t.het**
  - Tolerance in the heterogametic sex, that is t.het=0.05 means that 5% of the heterogametic sex can be homozygous and still be regarded as consistent with a sex specific marker [default 0.1].

- **t.hom**
  - Tolerance in the homogametic sex, that is t.hom=0.05 means that 5% of the homogametic sex can be heterozygous and still be regarded as consistent with a sex specific marker [default 0.1].

- **t.pres**
  - Tolerance in presence, that is t.pres=0.05 means that a silicodart marker can be present in either of the sexes and still be regarded as a sex-linked marker [default 0.1].

- **plot.out**
  - Creates a plot that shows the heterozygosity of males and females at each loci be regarded as consistent with a sex specific marker [default TRUE].

- **plot_theme**
  - Theme for the plot. See Details for options [default theme_dartR()].

- **plot_colors**
  - List of three color names for the not sex-linked loci, for the sex-linked loci and for the area in which sex-linked loci appear [default three_colors].

- **verbose**
  - Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

### Details

Sex of the individuals for which sex is known with certainty can be provided via a factor (equal to the length of the number of individuals) or to be held in the variable x@other$ind.metrics$sex. Coding is: M for male, F for female, U or NA for unknown/missing. The script abbreviates the entries here to the first character. So, coding of 'Female' and 'Male' works as well. Character are also converted to upper cases.

**Function's output**

This function creates also a plot that shows the heterozygosity of males and females at each loci for SNP data or percentage of present/absent in the case of SilicoDArT data.

```

---

**gl.filter.taglength**  
*Filters loci in a genlight {adegenet} object based on sequence tag length*

---

**Description**

SNP datasets generated by DArT typically have sequence tag lengths ranging from 20 to 69 base pairs.

**Usage**

```r
gl.filter.taglength(x, lower = 20, upper = 69, verbose = NULL)
```

**Arguments**

- `x`  
  Name of the genlight object containing the SNP data [required].
- `lower`  
  Lower threshold value below which loci will be removed [default 20].
- `upper`  
  Upper threshold value above which loci will be removed [default 69].
- `verbose`  
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

**Value**

Returns a genlight object retaining loci with a sequence tag length in the range specified by the lower and upper threshold.

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**Examples**

```r
# SNP data
gl.report.taglength(testset.gl)
result <- gl.filter.taglength(testset.gl, lower=60)
gl.report.taglength(result)
# Tag P/A data
gl.report.taglength(testset.gs)
result <- gl.filter.taglength(testset.gs, lower=60)
gl.report.taglength(result)
```
**gl.fixed.diff**

*Generates a matrix of fixed differences and associated statistics for populations taken pairwise*

**Description**

This script takes SNP data or sequence tag P/A data grouped into populations in a genlight object (DArTSeq) and generates a matrix of fixed differences between populations taken pairwise.

**Usage**

```r
gl.fixed.diff(
  x,
  tloc = 0,
  test = FALSE,
  delta = 0.02,
  alpha = 0.05,
  reps = 1000,
  mono.rm = TRUE,
  pb = FALSE,
  verbose = NULL
)
```

**Arguments**

- **x**: Name of the genlight object containing SNP genotypes or tag P/A data (Silico-DArT) or an object of class 'fd' [required].
- **tloc**: Threshold defining a fixed difference (e.g. 0.05 implies 95:5 vs 5:95 is fixed) [default 0].
- **test**: If TRUE, calculate p values for the observed fixed differences [default FALSE].
- **delta**: Threshold value for the true population minor allele frequency (MAF) from which resultant sample fixed differences are considered true positives [default 0.02].
- **alpha**: Level of significance used to display non-significant differences between populations as they are compared pairwise [default 0.05].
- **reps**: Number of replications to undertake in the simulation to estimate probability of false positives [default 1000].
- **mono.rm**: If TRUE, loci that are monomorphic across all individuals are removed before beginning computations [default TRUE].
- **pb**: If TRUE, show a progress bar on time consuming loops [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
Details

A fixed difference at a locus occurs when two populations share no alleles or where all members of one population has a sequence tag scored, and all members of the other population has the sequence tag absent. The challenge with this approach is that when sample sizes are finite, fixed differences will occur through sampling error, compounded when many loci are examined. Simulations suggest that sample sizes of n1=5 and n2=5 are adequate to reduce the probability of [experiment-wide] type 1 error to negligible levels [ploidy=2]. A warning is issued if comparison between two populations involves sample sizes less than 5, taking into account allele drop-out.

Optionally, if test=TRUE, the script will test the fixed differences between final OTUs for statistical significance, using simulation, and then further amalgamate populations that for which there are no significant fixed differences at a specified level of significance (alpha). To avoid conflation of true fixed differences with false positives in the simulations, it is necessary to decide a threshold value (delta) for extreme true allele frequencies that will be considered fixed for practical purposes. That is, fixed differences in the sample set will be considered to be positives (not false positives) if they arise from true allele frequencies of less than 1-delta in one or both populations. The parameter delta is typically set to be small (e.g. delta = 0.02).

NOTE: The above test will only be calculated if tloc=0, that is, for analyses of absolute fixed differences. The test applies in comparisons of allopatric populations only. For sympatric populations, use gl.pval.sympatry().

An absolute fixed difference is as defined above. However, one might wish to score fixed differences at some lower level of allele frequency difference, say where percent allele frequencies are 95,5 and 5,95 rather than 100:0 and 0:100. This adjustment can be done with the tloc parameter. For example, tloc=0.05 means that SNP allele frequencies of 95,5 and 5,95 percent will be regarded as fixed when comparing two populations at a locus.

Value

A list of Class ‘fd’ containing the gl object and square matrices, as follows:

1. $gl – the output genlight object;
2. $fd – raw fixed differences;
3. $pcfd – percent fixed differences;
4. $nobs – mean no. of individuals used in each comparison;
5. $nloc – total number of loci used in each comparison;
6. $expfpos – if test=TRUE, the expected count of false positives for each comparison [by simulation];
7. $sdfpos – if test=TRUE, the standard deviation of the count of false positives for each comparison [by simulation];
8. $prob – if test=TRUE, the significance of the count of fixed differences [by simulation])

**gl.fst.pop**

Calculates a pairwise Fst values for populations in a genlight object

**Description**

This script calculates pairwise Fst values based on the implementation in the StAMPP package (?stamppFst). It allows to run bootstrap to estimate probability of Fst values to be different from zero. For detailed information please check the help pages (?stamppFst).

**Usage**

```
gl.fst.pop(x, nboots = 100, percent = 95, nclusters = 1, verbose = NULL)
```

**Arguments**

- **x**  
  Name of the genlight containing the SNP genotypes [required].
- **nboots**  
  Number of bootstraps to perform across loci to generate confidence intervals and p-values [default 100].
- **percent**  
  Percentile to calculate the confidence interval around [default 95].
- **nclusters**  
  Number of processor threads or cores to use during calculations [default 1].
- **verbose**  
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

**Value**

A matrix of distances between populations (class dist), if nboots =1, otherwise a list with Fsts (in a matrix), Pvalues (a matrix of pvalues), Bootstraps results (data frame of all runs). Hint: Use as.matrix(as.dist(fsts)) if you want to have a squared matrix with symmetric entries returned, instead of a dist object.

gl.genleastcost

**Performs least-cost path analysis based on a friction matrix**

**Description**

This function calculates the pairwise distances (Euclidean, cost path distances and genetic distances) of populations using a friction matrix and a spatial genind object. The genind object needs to have coordinates in the same projected coordinate system as the friction matrix. The friction matrix can be either a single raster or a stack of several layers. If a stack is provided the specified cost distance is calculated for each layer in the stack. The output of this function can be used with the functions wassermann or lgrMMRR to test for the significance of a layer on the genetic structure.

**Usage**

```r
gl.genleastcost(
  x,
  fric.raster,
  gen.distance,
  NN = NULL,
  pathtype = "leastcost",
  plotpath = TRUE,
  theta = 1,
  verbose = NULL
)
```

**Arguments**

- `x` A spatial genind object. See ?popgenreport how to provide coordinates in genind objects [required].
- `fric.raster` A friction matrix [required].
- `NN` Number of neighbours used when calculating the cost distance (possible values 4, 8 or 16). As the default is NULL a value has to be provided if pathtype='leastcost'. NN=8 is most commonly used. Be aware that linear structures may cause artefacts in the least-cost paths, therefore inspect the actual least-cost paths in the provided output [default NULL].
- `pathtype` Type of cost distance to be calculated (based on function in the gdistance package. Available distances are 'leastcost', 'commute' or 'rSPDistance'. See functions in the gdistance package for further explanations. If the path type is set to 'leastcost' then paths and also pathlength are returned [default 'leastcost'].
- `plotpath` switch if least cost paths should be plotted (works only if pathtype='leastcost'. Be aware this slows down the computation, but it is recommended to do this to check least cost paths visually.
theta  value needed for rSPDistance function. See rSPDistance in package gdistance [default 1].

verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

Returns a list that consists of four pairwise distance matrices (Euclidean, Cost, length of path and genetic) and the actual paths as spatial line objects.

## End(Not run)
Calculates an identity by descent matrix

Description

This function calculates the mean probability of identity by descent (IBD) across loci that would result from all the possible crosses of the individuals analyzed. IBD is calculated by an additive relationship matrix approach developed by Endelman and Jannink (2012) as implemented in the function A.mat (package rrBLUP).

Usage

```r
gl.grm(
  x,
  plothemeatmap = TRUE,
  palette_discrete = discrete_palette,
  palette_convergent = convergent_palette,
  legendx = 0,
  legendy = 1,
  verbose = NULL,
  ...
)
```

Arguments

- `x` Name of the genlight object containing the SNP data [required].
- `plothemeatmap` A switch if a heatmap should be shown [default TRUE].
- `palette_discrete` A discrete palette for the color of populations or a list with as many colors as there are populations in the dataset [default discrete_palette].
- `palette_convergent` A convergent palette for the IBD values [default convergent_palette].
- `legendx` x coordinates for the legend [default 0].
- `legendy` y coordinates for the legend [default 1].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
- `...` Parameters passed to function A.mat from package rrBLUP.

Details

Two or more alleles are identical by descent (IBD) if they are identical copies of the same ancestral allele in a base population. The additive relationship matrix is a theoretical framework for estimating a relationship matrix that is consistent with an approach to estimate the probability that the alleles at a random locus are identical in state (IBS).
This function also plots a heatmap, and a dendrogram, of IBD values where each diagonal element has a mean that equals 1+f, where f is the inbreeding coefficient (i.e. the probability that the two alleles at a randomly chosen locus are IBD from the base population). As this probability lies between 0 and 1, the diagonal elements range from 1 to 2. Because the inbreeding coefficients are expressed relative to the current population, the mean of the off-diagonal elements is -(1+f)/n, where n is the number of loci. Individual names are shown in the margins of the heatmap and colors represent different populations.

Value

An identity by descent matrix

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

gl.grm.network

Other inbreeding functions: gl.grm.network()

Examples

gl.grm(bandicoot.gl[1:20,])
Usage

```r
gl.grm.network(
  G,
  x,
  method = "fr",
  node.size = 6,
  node.label = TRUE,
  node.label.size = 2,
  node.label.color = "black",
  relatedness_factor = 0.25,
  title = "Network based on a genomic relationship matrix",
  palette_discrete = discrete_palette,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- **G** | A genomic relationship matrix (GRM) generated by `gl.grm` [required].
- **x** | A genlight object from which the G matrix was generated [required].
- **method** | One of 'fr', 'kk', 'gh' or 'mds' [default 'fr'].
- **node.size** | Size of the symbols for the network nodes [default 6].
- **node.label** | TRUE to display node labels [default TRUE].
- **node.label.size** | Size of the node labels [default 3].
- **node.label.color** | Color of the text of the node labels [default 'black'].
- **relatedness_factor** | Factor of relatedness [default 0.5].
- **title** | Title for the plot [default 'Network based on genomic relationship matrix'].
- **palette_discrete** | A discrete palette for the color of populations or a list with as many colors as there are populations in the dataset [default discrete_palette].
- **save2tmp** | If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose** | Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

As identity by descent is not an absolute state, but is relative to a reference population for which there is generally little information, we can estimate the kinship of a pair of individuals only relative to some other quantity (Goudet et al., 2018). In this script, we use the average inbreeding coefficient (1-f) of the diagonal elements as the reference value. This reference value is then subtracted from the inbreeding coefficient of each pair of distinct individuals. This approach is similar to the used by Goudet et al. (2018).
Four layout options are implemented in this function:

- 'fr' Fruchterman-Reingold layout `layout_with_fr` (package igraph)
- 'kk' Kamada-Kawai layout `layout_with_kk` (package igraph)
- 'gh' Graphopt layout `layout_with_graphopt` (package igraph)
- 'mds' Multidimensional scaling layout `layout_with_mds` (package igraph)

The threshold for relatedness to be represented as a link in the network is specified as a quantile. Those relatedness measures above the quantile are plotted as links, those below the quantile are not. Often you are looking for relatedness outliers in comparison with the overall relatedness among individuals, so a very conservative quantile is used (e.g. 0.004), but ultimately, this decision is made as a matter of trial and error. One way to approach this trial and error is to try to achieve a sparse set of links between unrelated ‘background’ individuals so that the stronger links are preferentially shown.

**Value**

A network plot showing relatedness between individuals

**Author(s)**

**Value**

A simple vector whit Ho for each loci

**Author(s)**

Bernd Gruber (bugs? Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))
Performs Hardy-Weinberg tests over loci and populations

Description

Hardy-Weinberg tests are performed for each loci in each of the populations as defined by the pop slot in a genlight object.

Usage

```r
gl.hwe.pop(
  x,
  alpha_val = 0.05,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = c("gray90", "deeppink"),
  HWformat = FALSE,
  verbose = NULL
)
```

Arguments

- `x`: A genlight object with a population defined [pop(x) does not return NULL].
- `alpha_val`: Level of significance for testing [default 0.05].
- `plot.out`: If TRUE, returns a plot object compatible with ggplot, otherwise returns a dataframe [default TRUE].
- `plot_theme`: User specified theme [default theme_dartR()].
- `plot_colors`: Vector with two color names for the borders and fill [default two_colors]. [default discrete_palette].
- `HWformat`: Switch if data should be returned in HWformat (counts of Genotypes to be used in package HardyWeinberg)
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

This function employs the HardyWeinberg package, which needs to be installed. The function that is used is HWExactStats, but there are several other great functions implemented in the package regarding HWE. Therefore, this function can return the data in the format expected by the HWE package expects, via HWformat=TRUE and then use this to run other functions of the package.

This function performs a HWE test for every population (rows) and loci (columns) and returns a true false matrix. True is reported if the p-value of an HWE-test for a particular loci and population was below the specified threshold (alpha_val, default=0.05). The thinking behind this approach is that loci that are not in HWE in several populations have most likely to be treated (e.g. filtered if loci under selection are of interest). If plot=TRUE a barplot on the loci and the sum of deviation
over all population is returned. Loci that deviate in the majority of populations can be identified via colSums on the resulting matrix.

Plot themes can be obtained from

- https://ggplot2.tidyverse.org/reference/ggtheme.html and
- https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Resultant ggplots and the tabulation are saved to the session’s temporary directory.

Value

The function returns a list with up to three components:

- ‘HWE’ is the matrix over loci and populations
- 'plot' is a plot (ggplot) which shows the significant results for population and loci (can be amended further using ggplot syntax)
- ‘HWEformat=TRUE’ the 'HWformat' entails SNP data for each population in 'HardyWeinberg'-format to be used with other functions of the package (e.g. HWPerm or HWExactPrevious).

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

out <- gl.hwe.pop(bandicoot.gl[,1:33], alpha_val=0.05, plot.out=TRUE, HWformat=FALSE)

gl.ibd

Performs isolation by distance analysis

Description

This function performs an isolation by distance analysis based on a Mantel test and also produces an isolation by distance plot. If a genlight object with coordinates is provided, then an Euclidean and genetic distance matrices are calculated.

Usage

gl.ibd(
x = NULL,
distance = "Fst",
coordinates = "latlon",
Dgen = NULL,
Dgeo = NULL,
Dgeo_trans = "log(Dgeo)",
Dgen_trans = "Dgen",
permutations = 999,
Arguments

- **x**: Genlight object. If provided a standard analysis on \(F_{st}/1-F_{st}\) and \(\log(\text{distance})\) is performed [required].

- **distance**: Type of distance that is calculated and used for the analysis. Can be either population based \(F_{st}\) [stamppFst], \(D\) [stamppNeisD] or individual based \(\text{propShared}\), [gl.propShared], \(\text{euclidean}\) [gl.dist.ind, method='Euclidean'] [default "Fst"].

- **coordinates**: Can be either 'latlon', 'xy' or a two column data.frame with column names 'lat', 'lon', 'x', 'y'. Coordinates are provided via gl@other$latlon ['latlon'] or via gl@other$xy ['xy']. If latlon data will be projected to meters using Mercator system [google maps] or if xy then distance is directly calculated on the coordinates.

- **Dgen**: Genetic distance matrix if no genlight object is provided [default NULL].

- **Dgeo**: Euclidean distance matrix if no genlight object is provided [default NULL].

- **Dgeo_trans**: Transformation to be used on the Euclidean distances. see Dgen_trans [default 'log(Dgeo)'].

- **Dgen_trans**: You can provide a formula to transform the genetic distance. For example Rousset (see below) suggests to study \(F_{st}/(1-F_{st})\) against log transformed distances as this is the expectations of \(F_{st}\) versus distances in the case of a stepping stone model. The transformation can be applied as a formula using Dgen as the variable to be transformed. So, for the \(F_{st}\) transformation of Rousset use \(\text{Dgen_trans} = \text{Dgen}/(1-\text{Dgen})\). Any valid R expression can be used here. [default 'Dgen', which is the identity function.]

- **permutations**: Number of permutations in the Mantel test [default 999].

- **plot.out**: Should an isolation by distance plot be returned [default TRUE].

- **paircols**: Should pairwise dots colored by 'population'/'individual pairs [default 'pop']. You can color pairwise individuals by pairwise population colors.

- **plot_theme**: Theme for the plot. See details for options [default theme_dartR()].

- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].

- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

Currently pairwise \(F_{st}\) and \(D\) between populations and 1-\(\text{propShared}\) and Euclidean distance between individuals are implemented. Coordinates are expected as lat long and converted to Google
Earth Mercator projection. If coordinates are already projected, provide them at the x@other$xy slot.

You can provide also your own genetic and Euclidean distance matrices. The function is based on the code provided by the adegenet tutorial (http://adegenet.r-forge.r-project.org/files/tutorial-basics.pdf), using the functions mantel (package vegan), stamppFst, stamppNeisD (package StAMPP) and gl.propShared or gl.dist.ind. For transformation you need to have the dismo package installed. As a new feature you can plot pairwise relationship using double colored points (paircols=TRUE). Pairwise relationship can be visualised via populations or individuals, depending which distance is calculated. Please note: Often a problem arises, if an individual based distance is calculated (e.g. propShared) and some individuals have identical coordinates as this results in distances of zero between those pairs of individuals. If the standard transformation \[\log(Dgeo)\] is used, this results in an infinite value, because of trying to calculate \[\log(0)\]. To avoid this, the easiest fix is to change the transformation from \[\log(Dgeo)\] to \[\log(Dgeo+1)\] or you could add some "noise" to the coordinates of the individuals (e.g. \(+/- 1m\), but be aware if you use lat lon then you rather want to add \(+0.00001\) degrees or so).

Value

Returns a list of the following components: Dgen (the genetic distance matrix), Dgeo (the Euclidean distance matrix), Mantel (the statistics of the Mantel test).

mantel, stamppFst

Examples

#only first 100 loci
ibd <- gl.ibd(bandicoot.gl[,1:100])
#because of speed only the first 100 loci
ibd <- gl.ibd(bandicoot.gl[,1:10], Dgeo_trans='log(Dgeo)', Dgen_trans='Dgen/(1-Dgen)')
#because of speed only the first 10 individuals
ibd <- gl.ibd(bandicoot.gl[1:10,], distance='euclidean', paircols='pop', Dgeo_trans='Dgeo')
gl.impute  

Imputes missing data

Description

This function imputes genotypes on a population-by-population basis, where populations can be considered panmictic, or imputes the state for presence-absence data.

Usage

\[
\text{gl.impute(} \\
x, \\
\text{method = "neighbour",} \\
\text{fill.residual = TRUE,} \\
\text{parallel = FALSE,} \\
\text{verbose = NULL} \\
\text{)}
\]

Arguments

- **x**  
  Name of the genlight object containing the SNP or presence-absence data [required].

- **method**  
  Imputation method, either "frequency" or "HW" or "neighbour" or "random" [default "HW"].

- **fill.residual**  
  Should any residual missing values remaining after imputation be set to 0, 1, 2 at random, taking into account global allele frequencies at the particular locus [default TRUE].

- **parallel**  
  A logical indicating whether multiple cores -if available- should be used for the computations (TRUE), or not (FALSE); requires the package parallel to be installed [default FALSE].

- **verbose**  
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

We recommend that imputation be performed on sampling locations, before any aggregation. Imputation is achieved by replacing missing values using either of two methods:

- If "frequency", genotypes scored as missing at a locus in an individual are imputed using the average allele frequencies at that locus in the population from which the individual was drawn.
- If "HW", genotypes scored as missing at a locus in an individual are imputed by sampling at random assuming Hardy-Weinberg equilibrium. Applies only to genotype data.
- If "neighbour", substitute the missing values for the focal individual with the values taken from the nearest neighbour. Repeat with next nearest and so on until all missing values are replaced.
• if "random", missing data are substituted by random values (0, 1 or 2).

The nearest neighbour is the one with the smallest Euclidean distance in all the dataset.

The advantage of this approach is that it works regardless of how many individuals are in the population to which the focal individual belongs, and the displacement of the individual is haphazard as opposed to:

(a) Drawing the individual toward the population centroid (HW and Frequency).
(b) Drawing the individual toward the global centroid (glPCA).

Note that loci that are missing for all individuals in a population are not imputed with method 'frequency' or 'HW'. Consider using the function `gl.filter.allna` with by.pop=TRUE to remove them first.

Value

A genlight object with the missing data imputed.

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

Examples

```r
# SNP genotype data
gl <- gl.filter.callrate(platypus.gl, threshold=0.95)
gl <- gl.filter.allna(gl)
gl <- gl.impute(gl, method="neighbour")

# Sequence Tag presence-absence data
gs <- gl.filter.callrate(testset.gs, threshold=0.95)
gl <- gl.filter.allna(gl)
gs <- gl.impute(gs, method="neighbour")
```

---

gl.install.vanilla.dartR

Installs all required packages for using all functions available in dartR

Description

The function compares the installed packages with the the currently available ones on CRAN. Be aware this function only works if a version of dartR is already installed on your system. You can choose if you also want to have a specific version of dartR installed ("CRAN", "master", "beta" or "dev"). 'master', 'beta' and 'dev' are installed from Github. Be aware that the dev version from github is not fully tested and most certainly will contain untested functions.

Usage

```r
gl.install.vanilla.dartR(flavour = NULL, verbose = NULL)
```
Arguments

flavour  The version of R you want to install. If NULL then only packages needed for the current version will be installed. If 'CRAN' current CRAN version will be installed. 'master' installs the GitHub master branch, 'beta' installs the latest stable version, and 'dev' installs the experimental development branch from GitHub [default NULL].

verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

Returns a message if the installation was successful/required.

Author(s)

Custodian: Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

---

Description

This function combines two genlight objects and their associated metadata. The history associated with the two genlight objects is cleared from the new genlight object. The individuals/samples must be the same in each genlight object.

The function is typically used to combine datasets from the same service where the files have been split because of size limitations. The data is read in from multiple csv files, then the resultant genlight objects are combined.

Usage

```r
gl.join(x1, x2, verbose = NULL)
```

Arguments

- `x1` Name of the first genlight object [required].
- `x2` Name of the first genlight object [required].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

A new genlight object

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr
Examples

```r
x1 <- testset.gl[,1:100]
x1@other$loc.metrics <- testset.gl@other$loc.metrics[1:100,]
nLoc(x1)
x2 <- testset.gl[,101:150]
x2@other$loc.metrics <- testset.gl@other$loc.metrics[101:150,]
nLoc(x2)
gl <- gl.join(x1, x2, verbose=2)
nLoc(gl)
```

---

**gl.keep.ind**

*Removes all but the specified individuals from a genlight (adegenet) object*

**Description**

The script, having deleted individuals, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using gl.filter.monomorphs.r). The script also optionally recalculates statistics made redundant by the deletion of individuals from the dataset.

The script returns a genlight object with the individuals deleted and, optionally, the recalculated locus metadata.

**Usage**

```r
gl.keep.ind(x, ind.list, recalc = FALSE, mono.rm = FALSE, verbose = NULL)
```

**Arguments**

- **x**
  Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].
- **ind.list**
  A list of individuals to be removed [required].
- **recalc**
  Recalculate the locus metadata statistics [default FALSE].
- **mono.rm**
  Remove monomorphic loci [default FALSE].
- **verbose**
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Value**

A genlight object with the reduced data

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**See Also**

- `gl.drop.ind` to drop rather than keep specified individuals
**Examples**

```r
# SNP data
gl2 <- gl.keep.loc(testset.gl, ind.list=c('AA019073', 'AA004859'))  
# Tag P/A data
gs2 <- gl.keep.loc(testset.gs, ind.list=c('AA020656', 'AA19077', 'AA004859'))
```

---

**Description**

The script returns a genlight object with the all but the specified loci deleted.

**Usage**

```r
gl.keep.loc(x, loc.list = NULL, first = NULL, last = NULL, verbose = NULL)
```

**Arguments**

- **x**: Name of the genlight object containing SNP genotypes or presence/absence data [required].
- **loc.list**: A list of loci to be kept [required, if loc.range not specified].
- **first**: First of a range of loci to be kept [required, if loc.list not specified].
- **last**: Last of a range of loci to be kept [if not specified, last locus in the dataset].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity]

**Value**

A genlight object with the reduced data

**Author(s)**

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

**See Also**

*gl.drop.loc* to drop rather than keep specified loci

---

**Examples**

```r
# SNP data
gl2 <- gl.keep.loc(testset.gl, loc.list=c('100051468|42-A/T', '100049816-51-A/G'))  
# Tag P/A data
gs2 <- gl.keep.loc(testset.gs, loc.list=c('20134188', '19249144'))
```
**gl.keep.pop**

*Removes all but the specified populations from a genlight object*

**Description**

Individuals are assigned to populations based on the specimen metadata data file (csv) used with `gl.read.dart()`. The script, having deleted the specified populations, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using `gl.filter.monomorphs.r`). The script also optionally recalculates statistics made redundant by the deletion of individuals from the dataset. The script returns a genlight object with the new population assignments and the recalculated locus metadata.

**Usage**

```r
gl.keep.pop(
  x,
  pop.list,
  as.pop = NULL,
  recalc = FALSE,
  mono.rm = FALSE,
  verbose = NULL
)
```

**Arguments**

- **x**: Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].
- **pop.list**: A list of populations to be kept [required].
- **as.pop**: Assign another metric to represent population [default NULL].
- **recalc**: Recalculate the locus metadata statistics [default FALSE].
- **mono.rm**: Remove monomorphic loci [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`]

**Value**

A genlight object with the reduced data

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**See Also**

- `gl.drop.pop` to drop rather than keep specified populations
Examples

```r
# SNP data
gl2 <- gl.keep.pop(testset.gl, pop.list=c('EmsubRopeMata', 'EmvicVictJasp'))
gl2 <- gl.keep.pop(testset.gl, pop.list=c('EmsubRopeMata', 'EmvicVictJasp'),
                   mono.rm=TRUE, recalc=TRUE)
gl2 <- gl.keep.pop(testset.gl, pop.list=c('Female'), as.pop='sex')
# Tag P/A data
gs2 <- gl.keep.pop(testset.gs, pop.list=c('EmsubRopeMata', 'EmvicVictJasp'))
```

---

**gl.LDNe**

*Estimates effective population size using the Linkage Disequilibrium method based on NeEstimator (V2)*

Description

This function is basically a convenience function that runs the LD Ne estimator using Neestima-
tor2 ([http://www.molecularfisherieslaboratory.com.au/neestimator-software/](http://www.molecularfisherieslaboratory.com.au/neestimator-software/)) within R using the provided genlight object. To be able to do so, the software has to be downloaded from their website and the appropriate executable Ne2-1 has to be copied into the path as specified in the function (see example below).

Usage

```r
gl.LDNe(
  x,  # Name of the genlight object containing the SNP data [required].
  outfile = "genepopLD.txt",  # File name of the output file with all results from Neestimator 2 [default 'genepopLD.txt'].
  outpath = tempdir(),  # Path where to save the output file. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory [default tempdir(), mandated by CRAN].
  neest.path = getwd(),
  critical = 0,
  singleton.rm = TRUE,
  mating = "random",
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors_pop = discrete_palette,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- **x**
  - Name of the genlight object containing the SNP data [required].
- **outfile**
  - File name of the output file with all results from Neestimator 2 [default 'genepopLD.txt'].
- **outpath**
  - Path where to save the output file. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory [default tempdir(), mandated by CRAN].
neest.path    Path to the folder of the NE2-1 file. Please note there are 3 different executables depending on your OS: Ne2-1.exe (=Windows), Ne2-1M (=Mac), Ne2-1L (=Linux). You only need to point to the folder (the function will recognise which OS you are running) [default getwd()].
critical    (vector of) Critical values that are used to remove alleles based on their minor allele frequency. This can be done before using the gl.filter.maf function, therefore the default is set to 0 (no loci are removed). To run for MAF 0 and MAF 0.05 at the same time specify: critical = c(0,0.05) [default 0].
singleton.rm    Whether to remove singleton alleles [default TRUE].
mating    Formula for Random mating='random' or monogamy= 'monogamy' [default 'random'].
plot.out    Specify if plot is to be produced [default TRUE].
plot_theme    User specified theme [default theme_dartR()].
plot_colors_pop    A discrete palette for population colors or a list with as many colors as there are populations in the dataset [default discrete_palette].
save2tmp    If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose    Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

Dataframe with the results as table

Author(s)

Custodian: Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

Examples

## Not run:
# SNP data (use two populations and only the first 100 SNPs)
pops <- possums.gl[1:60,1:100]
nes <- gl.LDNe(pops, outfile="popsLD.txt", outpath=tempdir(),
neest.path = "/path_to Ne-21",
critical=c(0,0.05), singleton.rm=TRUE, mating='random')
nes

## End(Not run)
**gl.list.reports**

*Prints dartR reports saved in tempdir*

**Description**

Prints dartR reports saved in tempdir

**Usage**

```r
gl.list.reports()
```

**Value**

Prints a table with all reports saved in tempdir. Currently the style cannot be changed.

**Author(s)**

Bernd Gruber & Luis Mijangos (bugs? Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

**See Also**

`gl.print.reports`

**Examples**

```r
## Not run:
gl.report.callrate(testset.gl,save2tmp=TRUE)
gl.list.reports()
## End(Not run)
```

---

**gl.load**

*Loads an object from compressed binary format produced by gl.save()*

**Description**

This is a wrapper for `readRDS()`

**Usage**

```r
gl.load(file, verbose = NULL)
```

**Arguments**

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>file</code></td>
<td>Name of the file to receive the binary version of the object [required].</td>
</tr>
<tr>
<td><code>verbose</code></td>
<td>Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using <code>gl.set.verbosity</code>].</td>
</tr>
</tbody>
</table>
**Details**

The script loads the object from the current workspace and returns the gl object.

**Value**

The loaded object

**Author(s)**

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

**See Also**

*gl.save*

**Examples**

```r
gl.save(testset.gl, file.path(tempdir(), 'testset.rds'))
```

```r
gl <- gl.load(file.path(tempdir(), 'testset.rds'))
```

---

**gl.make.recode.ind**

*Creates a proforma recode_ind file for reassigning individual (=specimen) names*

**Description**

Renaming individuals may be required when there have been errors in labelling arising in the process from sample to DArT files. There may be occasions where renaming individuals is required for preparation of figures. Caution needs to be exercised because of the potential for breaking the 'chain of evidence' between the samples themselves and the analyses. Recoding individuals can be done with a recode table (csv).

**Usage**

```r
gl.make.recode.ind(
  x,  
  out.recode.file = "default_recode_ind.csv",  
  outpath = tempdir(),  
  verbose = NULL  
)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data [required].
- `out.recode.file` File name of the output file (including extension) [default default_recode_ind.csv].
gl.make.recode.pop

outpath Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.

verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

This script facilitates the construction of a recode table by producing a proforma file with current individual (=specimen) names in two identical columns. Edit the second column to reassign individual names. Use keyword Delete to delete an individual.

Apply the recoding using gl.recode.ind(). Deleting individuals can potentially generate monomorphic loci or loci with all values missing. Clean this up with gl.filter.monomorphic().

Value

A vector containing the new individual names.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

result <- gl.make.recode.ind(testset.gl, out.recode.file = 'Emmac_recode_ind.csv', outpath = tempdir())

gl.make.recode.pop

Creates a proforma recode_pop_table file for reassigning population names

Description

Renaming populations may be required when there have been errors in assignment arising in the process from sample to DArT files or when one wishes to amalgamate populations, or delete populations. Recoding populations can also be done with a recode table (csv).

Usage

```r
gl.make.recode.pop(
x,
  out.recode.file = "recode_pop_table.csv",
  outpath = tempdir(),
  verbose = NULL
)
```
**Arguments**

- **x**: Name of the genlight object containing the SNP data [required].
- **out.recode.file**: File name of the output file (including extension) [default recode_pop_table.csv].
- **outpath**: Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Details**

This script facilitates the construction of a recode table by producing a proforma file with current population names in two identical columns. Edit the second column to reassign populations. Use keyword Delete to delete a population.

Apply the recoding using `gl.recode.pop()`.

**Value**

A vector containing the new population names.

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**Examples**

```r
gl.make.recode.pop(testset.gl,out.recode.file='test.csv',outpath=tempdir(),verbose=2)
```

---

**gl.map.interactive**

Creates an interactive map (based on latlon) from a genlight object

**Description**

Creates an interactive map (based on latlon) from a genlight object

**Usage**

```r
gl.map.interactive(
  x,
  matrix = NULL,
  standard = TRUE,
  symmetric = TRUE,
  pop.labels = TRUE,
  pop.labels.cex = 12,
  ind.circles = TRUE,
)```
ind.circle.cols = NULL,
ind.circle.cex = 10,
ind.circle.transparency = 0.8,
provider = "Esri.NatGeoWorldMap",
verbose = NULL)

Arguments

x
A genlight object (including coordinates within the latlon slot) [required].

matrix
A distance matrix between populations or individuals. The matrix is visualised
as lines between individuals/populations. If matrix is asymmetric two lines with
arrows are plotted [default NULL].

standard
If a matrix is provided line width will be standardised to be between 1 to 10, if
set to true, otherwise taken as given [default TRUE].

symmetric
If a symmetric matrix is provided only one line is drawn based on the lower
triangle of the matrix. If set to false arrows indicating the direction are used
instead [default TRUE].

pop.labels
Population labels at the center of the individuals of populations [default TRUE].

pop.labels.cex
Size of population labels [default 12].

ind.circles
Should individuals plotted as circles [default TRUE].

ind.circle.cols
colors off circles. Colors can be provided as usual by names (e.g. "black") and
are re-cycled. So a color c("blue","red") colors individuals alternatively between
blue and red using the genlight object order of individuals. For transparency see
parameter ind.circle.transparency. Defaults to rainbow colors by population if
not provided. If you want to have your own colors for each population, check
the platypus.gl example below.

ind.circle.cex
(size or circles in pixels ). Defaults to 10.

ind.circle.transparency
Transparency of circles between 0=invisible and 1=no transparency. Defaults to
0.8.

provider
Passed to leaflet [default "Esri.NatGeoWorldMap"]').

verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress
and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

A wrapper around the leaflet package. For possible background maps check as specified via the

Value

plots a map
Author(s)
Bernd Gruber – Post to https://groups.google.com/d/forum/dartr

Examples

```r
gl.map.interactive(bandicoot.gl)
cols <- c("red","blue","yellow")[as.numeric(pop(platypus.gl))]
gl.map.interactive(platypus.gl, ind.circle.cols=cols, ind.circle.cex=10, ind.circle.transparency=0.5)
```

---

**gl.map.structure**  
Maps a STRUCTURE plot using a genlight object

**Description**
This function takes the output of plotstructure (the q matrix) and maps the q-matrix across using the population centers from the genlight object that was used to run the structure analysis via `gl.run.structure`) and plots the typical structure bar plots on a spatial map, providing a barplot for each subpopulation. Therefore it requires coordinates from a genlight object. This kind of plots should support the interpretation of the spatial structure of a population, but in principle is not different from `gl.plot.structure`

**Usage**

```r
gl.map.structure(
  qmat, 
  x, 
  K, 
  provider = "Esri.NatGeoWorldMap", 
  scalex = 1, 
  scaley = 1, 
  movepops = NULL, 
  pop.labels = TRUE, 
  pop.labels.cex = 12
)
```

**Arguments**

- **qmat**  
  Q-matrix from a structure run followed by a clumpp run object [from `gl.run.structure` and `gl.plot.structure`] [required].

- **x**  
  Name of the genlight object containing the coordinates in the `@other$latlon` slot to calculate the population centers [required].

- **K**  
  The number for K to be plotted [required].

- **provider**  
  Provider passed to leaflet. Check `providers` for a list of possible backgrounds [default "Esri.NatGeoWorldMap"].

- **scalex**  
  Scaling factor to determine the size of the bars in x direction [default 1].
scaley

Scaling factor to determine the size of the bars in y direction [default 1].

movepops

A two-dimensional data frame that allows to move the center of the barplots manually in case they overlap. Often if populations are horizontally close to each other. This needs to be a data.frame of the dimensions [rows=number of populations, columns = 2 (lon/lat)]. For each population you have to specify the x and y (lon and lat) units you want to move the center of the plot, (see example for details) [default NULL].

pop.labels

Switch for population labels below the parplots [default TRUE].

pop.labels.cex

Size of population labels [default 12].

Details

Creates a mapped version of structure plots. For possible background maps check as specified via the provider: http://leaflet-extras.github.io/leaflet-providers/preview/index.html. You may need to adjust scalex and scaley values [default 1], as the size depends on the scale of the map and the position of the populations.

Value

An interactive map that shows the structure plots broken down by population.

returns the map and a list of the qmat split into sorted matrices per population. This can be used to create your own map.

### Examples

```r
## Not run:
#bc <- bandicoot.gl[,1:100]
#sr <- gl.run.structure(bc, k.range = 2:5, num.k.rep = 3, exec = './structure.exe')
#ev <- gl.evanno(sr)
#ev
#qmat <- gl.plot.structure(sr, k=2:4) #head(qmat)
#gl.map.structure(qmat, bc,K=3)
#gl.map.structure(qmat, bc,K=4)
#move population 4 (out of 5) 0.5 degrees to the right and populations 1
#0.3 degree to the north of the map.
#mp <- data.frame(lon=c(0,0,0,0.5,0), lat=c(-0.3,0,0,0,0))
#gl.map.structure(qmat, bc,K=4, movepops=mp)
## End(Not run)
```

---

### gl.merge.pop

Merges two or more populations in a genlight object into one population.

#### Description

Individuals are assigned to populations based on the specimen metadata data file (csv) used with `gl.read.dart()`.

This script assigns individuals from two nominated populations into a new single population. It can also be used to rename populations.

The script returns a genlight object with the new population assignments.

#### Usage

```r
gl.merge.pop(x, old = NULL, new = NULL, verbose = NULL)
```

#### Arguments

- `x`: Name of the genlight object containing SNP genotypes [required].
- `old`: A list of populations to be merged [required].
- `new`: Name of the new population [required].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`].

#### Value

A genlight object with the new population assignments.

#### Author(s)

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)
Examples

gl <- gl.merge.pop(testset.gl, old=c('EmsubRopeMata','EmvicVictJasp'), new='Outgroup')

---

gl.nhybrids

Creates an input file for the program NewHybrids and runs it if NewHybrids is installed

Description

This function compares two sets of parental populations to identify loci that exhibit a fixed difference, returns an genlight object with the reduced data, and creates an input file for the program NewHybrids using the top 200 (or hard specified loc.limit) loci. In the absence of two identified parental populations, the script will select a random set 200 loci only (method='random') or the first 200 loci ranked on information content (method='AvgPIC').

A fixed difference occurs when a SNP allele is present in all individuals of one population and absent in the other. There is provision for setting a level of tolerance, e.g. threshold = 0.05 which considers alleles present at greater than 95 a fixed difference. Only the 200 loci are retained, because of limitations of NewHybrids.

If you specify a directory for the NewHybrids executable file, then the script will create the input file from the SNP data then run NewHybrids. If the directory is set to NULL, the execution will stop once the input file (default='nhyb.txt') has been written to disk. Note: the executable option will not work on a Mac; Mac users should generate the NewHybrids input file and run this on their local installation of NewHybrids.

Refer to the New Hybrids manual for further information on the parameters to set – http://ib.berkeley.edu/labs/slatkin/eriq/software/new_hybs_doc1_1Beta3.pdf

It is important to stringently filter the data on RepAvg and CallRate if using the random option. One might elect to repeat the analysis (method='random') and combine the resultant posterior probabilities should 200 loci be considered insufficient.

The F1 individuals should be homozygous at all loci for which the parental populations are fixed and different, assuming parental populations have been specified. Sampling errors can result in this not being the case, especially where the sample sizes for the parental populations are small. Alternatively, the threshold for posterior probabilities used to determine assignment (pprob) or the definition of a fixed difference (threshold) may be too lax. To assess the error rate in the determination of assignment of F1 individuals, a plot of the frequency of homozygous reference, heterozygotes and homozygous alternate (SNP) can be produced by setting plot=TRUE (the default).

Usage

gl.nhybrids(
  gl,
  outpath = tempdir(),
  p0 = NULL,
  p1 = NULL,
  threshold = 0,
  method = "random",
  plot = TRUE,
gl.nhybrids

```r
plot_theme = theme_dartR(),
plot_colors = two_colors,
pprob = 0.95,
nhyb.directory = NULL,
BurnIn = 10000,
sweeps = 10000,
GtypFile = "TwoGensGtypFreq.txt",
APriorFile = NULL,
PiPrior = "Jeffreys",
ThetaPrior = "Jeffreys",
verbose = NULL
)
```

### Arguments

- `gl` Name of the genlight object containing the SNP data [required].
- `output` Path where to save the output file [default tempdir()].
- `p0` List of populations to be regarded as parental population 0 [default NULL].
- `p1` List of populations to be regarded as parental population 1 [default NULL].
- `threshold` Sets the level at which a gene frequency difference is considered to be fixed [default 0].
- `method` Specifies the method (random or AvgPIC) to select 200 loci for NewHybrids [default random].
- `plot` If TRUE, a plot of the frequency of homozygous reference, heterozygotes and homozygous alternate (SNP) is produced for the F1 individuals [default TRUE, applies only if both parental populations are specified].
- `plot_theme` User specified theme [default theme_dartR()].
- `plot_colors` Vector with two color names for the borders and fill [default two_colors].
- `pprob` Threshold level for assignment to likelihood bins [default 0.95, used only if plot=TRUE].
- `nhyb.directory` Directory that holds the NewHybrids executable file e.g. C:/NewHybsPC [default NULL].
- `BurnIn` Number of sweeps to use in the burn in [default 10000].
- `sweeps` Number of sweeps to use in computing the actual Monte Carlo averages [default 10000].
- `GtypFile` Name of a file containing the genotype frequency classes [default TwoGensGtypFreq.txt].
- `APriorFile` Name of the file containing prior allele frequency information [default NULL].
- `PiPrior` Jeffreys-like priors or Uniform priors for the parameter pi [default Jeffreys].
- `ThetaPrior` Jeffreys-like priors or Uniform priors for the parameter theta [default Jeffreys].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
Value

The reduced genlight object, if parentals are provided; output of NewHybrids is saved to the working directory.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

References

Examples

```r
## Not run:
m <- gl.nhybrids(testset.gl,

outpath="D:/workspace", # Specify as necessary, usually getwd() [= workspace]
BurnIn=100,
sweeps=100,
verbose=3)
## End(Not run)
```

---

**gl.outflank**

Identifies loci under selection per population using the outflank method of Whitlock and Lotterhos (2015)

**Description**

Identifies loci under selection per population using the outflank method of Whitlock and Lotterhos (2015)

**Usage**

```r
gl.outflank(
  gi,
  plot = TRUE,
  LeftTrimFraction = 0.05,
  RightTrimFraction = 0.05,
  Hmin = 0.1,
  qthreshold = 0.05,
  ...
)
```
Arguments

gi A genlight or genind object, with a defined population structure [required].

plot A switch if a barplot is wanted [default TRUE].

LeftTrimFraction The proportion of loci that are trimmed from the lower end of the range of Fst before the likelihood function is applied [default 0.05].

RightTrimFraction The proportion of loci that are trimmed from the upper end of the range of Fst before the likelihood function is applied [default 0.05].

Hmin The minimum heterozygosity required before including calculations from a locus [default 0.1].

qthreshold The desired false discovery rate threshold for calculating q-values [default 0.05].

... additional parameters (see documentation of outflank on github).

Details

This function is a wrapper around the outflank function provided by Whitlock and Lotterhos. To be able to run this function the packages qvalue (from bioconductor) and outflank (from github) needs to be installed. To do so see example below.

Value

Returns an index of outliers and the full outflank list

References

Github repository: Whitlock & Lotterhos: https://github.com/whitlock/OutFLANK (Check the readme.pdf within the repository for an explanation. Be aware you now can run OutFLANK from a genlight object)

See Also

utils.outflank, utils.outflank.plotter, utils.outflank.MakeDiploidFSTMat

Examples

gl.outflank(bandicoot.gl, plot = TRUE)
Ordination applied to genotypes in a genlight object (PCA), in an fd object, or to a distance matrix (PCoA)

Description

This function takes the genotypes for individuals and undertakes a Pearson Principal Component analysis (PCA) on SNP or Tag P/A (SilicoDArT) data; it undertakes a Gower Principal Coordinate analysis (PCoA) if supplied with a distance matrix. Technically, any distance matrix can be represented in an ordinated space using PCoA.

Usage

gl.pcoa(
  x,
  nfactors = 5,
  correction = NULL,
  mono.rm = TRUE,
  parallel = FALSE,
  n.cores = 16,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)

Arguments

x Name of the genlight object or fd object containing the SNP data, or a distance matrix of type dist [required].
nfactors Number of axes to retain in the output of factor scores [default 5].
correction Method applied to correct for negative eigenvalues, either 'lingoes' or 'cailliez' [Default NULL].
mono.rm If TRUE, remove monomorphic loci [default TRUE].
parallel TRUE if parallel processing is required (does fail under Windows) [default FALSE].
n.cores Number of cores to use if parallel processing is requested [default 16].
plot.out If TRUE, a diagnostic plot is displayed showing a scree plot for the "informative" axes and a histogram of eigenvalues of the remaining "noise" axes [Default TRUE].
plot_theme Theme for the plot. See Details for options [default theme_dartR()].
plot_colors List of two color names for the borders and fill of the plot [default two_colors].
save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose

verbose= 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

The function is essentially a wrapper for glPca adegenet or pcoa {ape} with default settings apart from those specified as parameters in this function. Sources of stress in the visual representation

While, technically, any distance matrix can be represented in an ordinated space, the representation will not typically be exact. There are three major sources of stress in a reduced-representation of distances or dissimilarities among entities using PCA or PCoA. By far the greatest source comes from the decision to select only the top two or three axes from the ordinated set of axes derived from the PCA or PCoA. The representation of the entities such a heavily reduced space will not faithfully represent the distances in the input distance matrix simply because of the loss of information in deeper informative dimensions. For this reason, it is not sensible to be too precious about managing the other two sources of stress in the visual representation.

The measure of distance between entities in a PCA is the Pearson Correlation Coefficient, essentially a standardized Euclidean distance. This is both a metric distance and a Euclidean distance. In PCoA, the second source of stress is the choice of distance measure or dissimilarity measure. While any distance or dissimilarity matrix can be represented in an ordinated space, the distances between entities can be faithfully represented in that space (that is, without stress) only if the distances are metric. Furthermore, for distances between entities to be faithfully represented in a rigid Cartesian space, the distance measure needs to be Euclidean. If this is not the case, the distances between the entities in the ordinated visualized space will not exactly represent the distances in the input matrix (stress will be non-zero). This source of stress will be evident as negative eigenvalues in the deeper dimensions.

A third source of stress arises from having a sparse dataset, one with missing values. This affects both PCA and PCoA. If the original data matrix is not fully populated, that is, if there are missing values, then even a Euclidean distance matrix will not necessarily be ‘positive definite’. It follows that some of the eigenvalues may be negative, even though the distance metric is Euclidean. This issue is exacerbated when the number of loci greatly exceeds the number of individuals, as is typically the case when working with SNP data. The impact of missing values can be minimized by stringently filtering on Call Rate, albeit with loss of data. An alternative is given in a paper ‘Honey, I shrunk the sample covariance matrix’ and more recently by Ledoit and Wolf (2018), but their approach has not been implemented here.

The good news is that, unless the sum of the negative eigenvalues, arising from a non-Euclidean distance measure or from missing values, approaches those of the final PCA or PCoA axes to be displayed, the distortion is probably of no practical consequence and certainly not comparable to the stress arising from selecting only two or three final dimensions out of several informative dimensions for the visual representation.

Function’s output

Two diagnostic plots are produced. The first is a Scree Plot, showing the percentage variation explained by each of the PCA or PCoA axes, for those axes that explain more than the original variables (loci) on average. That is, only informative axes are displayed. The scree plot informs the number of dimensions to be retained in the visual summaries. As a rule of thumb, axes with more than 10

The second graph shows the distribution of eigenvalues for the remaining uninformative (noise) axes, including those with negative eigenvalues.
Action is recommended (verbose >= 2) if the negative eigenvalues are dominant, their sum approaching in magnitude the eigenvalues for axes selected for the final visual solution.

Output is a glPca object conforming to adegenet::glPca but with only the following retained.

- $call - The call that generated the PCA/PCoA
- $eig - Eigenvalues – All eigenvalues (positive, null, negative).
- $scores - Scores (coefficients) for each individual
- $loadings - Loadings of each SNP for each principal component

Plots and table were saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in

- https://ggplot2.tidyverse.org/reference/ggtheme.html and
- https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

PCA was developed by Pearson (1901) and Hotelling (1933), whilst the best modern reference is Jolliffe (2002). PCoA was developed by Gower (1966) while the best modern reference is Legendre & Legendre (1998).

Value

An object of class pcoa containing the eigenvalues and factor scores

```

---

**gl.pcoa.plot**

Bivariate or trivariate plot of the results of an ordination generated using `gl.pcoa()`

Description

This script takes output from the ordination generated by `gl.pcoa()` and plots the individuals classified by population.

Usage

```r
gl.pcoa.plot(
  glPca, 
  x, 
  scale = FALSE, 
  ellipse = FALSE, 
  plevel = 0.95, 
)```

pop.labels = "pop",
interactive = FALSE,
as.pop = NULL,
hadjust = 1.5,
vadjust = 1,
xaxis = 1,
yaxis = 2,
zaxis = NULL,
pt.size = 2,
pt.colors = NULL,
pt.shapes = NULL,
label.size = 1,
axis.label.size = 1.5,
save2tmp = FALSE,
verbose = NULL
)

Arguments

**glPca**  
Name of the PCA or PCoA object containing the factor scores and eigenvalues [required].

**x**  
Name of the genlight object or fd object containing the SNP genotypes or Tag P/A (SilicoDArT) genotypes or the Distance Matrix used to generate the ordination [required].

**scale**  
If TRUE, scale the x and y axes in proportion to % variation explained [default FALSE].

**ellipse**  
If TRUE, display ellipses to encapsulate points for each population [default FALSE].

**plevel**  
Value of the percentile for the ellipse to encapsulate points for each population [default 0.95].

**pop.labels**  
How labels will be added to the plot [‘none’|’pop’|’legend’, default = ’pop’].

**interactive**  
If TRUE then the populations are plotted without labels, mouse-over to identify points [default FALSE].

**as.pop**  
Assign another metric to represent populations for the plot [default NULL].

**hadjust**  
Horizontal adjustment of label position in 2D plots [default 1.5].

**vadjust**  
Vertical adjustment of label position in 2D plots [default 1].

**xaxis**  
Identify the x axis from those available in the ordination (xaxis <= nfactors) [default 1].

**yaxis**  
Identify the y axis from those available in the ordination (yaxis <= nfactors) [default 2].

**zaxis**  
Identify the z axis from those available in the ordination for a 3D plot (zaxis <= nfactors) [default NULL].

**pt.size**  
Specify the size of the displayed points [default 2].

**pt.colors**  
Optionally provide a vector of nPop colors (run gl.select.colors() for color options) [default NULL].
pt.shapes  Optionally provide a vector of nPop shapes (run gl.select.shapes() for shape options) [default NULL].

label.size  Specify the size of the point labels [default 1].

axis.label.size  Specify the size of the displayed axis labels [default 1.5].

save2tmp  If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].

verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details
The factor scores are taken from the output of gl.pcoa() and the population assignments are taken from the original data file. In the bivariate plots, the specimens are shown optionally with adjacent labels and enclosing ellipses. Population labels on the plot are shuffled so as not to overlap (using package {directlabels}). This can be a bit clunky, as the labels may be some distance from the points to which they refer, but it provides the opportunity for moving labels around using graphics software (e.g. Adobe Illustrator).

3D plotting is activated by specifying a zaxis.

Any pair or trio of axes can be specified from the ordination, provided they are within the range of the nfactors value provided to gl.pcoa(). In the 2D plots, axes can be scaled to represent the proportion of variation explained. In any case, the proportion of variation explained by each axis is provided in the axis label.

Colors and shapes of the points can be altered by passing a vector of shapes and/or a vector of colors. These vectors can be created with gl.select.shapes() and gl.select.colors() and passed to this script using the pt.shapes and pt.colors parameters.

Points displayed in the ordination can be identified if the option interactive=TRUE is chosen, in which case the resultant plot is ggplotly() friendly. Identification of points is by moving the mouse over them. Refer to the plotly package for further information. The interactive option is automatically enabled for 3D plotting.

# color AND SHAPE ADJUSTMENTS
shp <- gl.select.shapes(select=c(16,17,17,0,2))
col <- gl.select.colors(library='brewer',palette='Spectral',ncolors=11,
select=c(1,9,3,11,11))

Description
This is a support script, to take SNP data or SilicoDArT presence/absence data grouped into populations in a genlight object (adegenet) and generate a table of allele frequencies for each population and locus.

Usage

```r
gl.percent.freq(x, verbose = NULL)
```

Arguments

- **x**: Name of the genlight object containing the SNP or Tag P/A (SilicoDArT) data [required].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

A matrix with allele (SNP data) or presence/absence frequencies (Tag P/A data) broken down by population and locus.
Author(s)

Custodian: Arthur Georges (Post to https://groups.google.com/d/forum/dartr)

Examples

```r
m <- gl.percent.freq(testset.gl)
```

---

**gl.play.history**  
*Replays the history and applies it to a genlight object*

**Description**

Replays the history and applies it to a genlight object.

**Usage**

```r
gl.play.history(x, history = NULL, verbose = 0)
```

**Arguments**

- `x`: A genlight object (with a history slot) [optional].
- `history`: If no history is provided the complete history of `x` is used (recreating the identical object `x`). If history is a vector it indicates which part of the history of `x` is used [c(1,3,4) uses the first, third and forth entry from `x@other$history`]. Or a simple link to a history slot of another genlight object (e.g. `codex2@other$history[c(1,4,5)]`). [optional].
- `verbose`: If set to one then history commands are printed, which may facilitate reading the output [default 0].

**Details**

This function basically allows to create a 'template history' (=set of filters) and apply them to any other genlight object. Histories can also be saved and loaded (see. `gl.save.history` and `gl.load.history`).

**Value**

Returns a genlight object that was created by replaying the provided applied to the genlight object `x`. Please note you can 'mix' histories or part of them and apply them to different genlight objects. If the history does not contain `gl.read.dart`, histories of `x` and history are concatenated.

**Author(s)**

Examples

```r
# Not run:
dartfile <- system.file("extdata", "testset_SNPs_2Row.csv", package="dartR")
metadata <- system.file("extdata", "testset_metadata.csv", package="dartR")
gl <- gl.read.dart(dartfile, ind.metafile = metadata, probar=FALSE)
gl2 <- gl.filter.callrate(gl, method="loc", threshold=0.9)
gl3 <- gl.filter.callrate(gl2, method="ind", threshold=0.95)
# Now 'replay' part of the history 'onto' another genlight object
# bc.fil <- gl.play.history(gl.compliance.check(bandicoot.gl),
# history=gl3@other$history[c(2,3)], verbose=1)
# gl.print.history(bc.fil)

# End(Not run)
```

---

### gl.plot.heatmap

**Represents a distance matrix as a heatmap**

**Description**

The script plots a heat map to represent the distances in the distance or dissimilarity matrix. This function is a wrapper for `heatmap.2` (package gplots).

**Usage**

```r
gl.plot.heatmap(D, palette_divergent = diverging_palette, verbose = NULL, ...)
```

**Arguments**

- `D` Name of the distance matrix or class fd object [required].
- `palette_divergent` A divergent palette for the distance values [default `diverging_palette`].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`]
- `...` Parameters passed to function `heatmap.2` (package gplots)

**Author(s)**

Custodian: Luis Mijangos – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**Examples**

```r
gl <- testset.gl[1:10,]
D <- dist(as.matrix(gl), upper=TRUE, diag=TRUE)
gl.plot.heatmap(D)
D2 <- gl.dist.pop(possums.gl)
gl.plot.heatmap(D2)
D3 <- gl.fixed.diff(testset.gl)
gl.plot.heatmap(D3)
```
gl.plot.network  

*Represents a distance or dissimilarity matrix as a network*

**Description**

This script takes a distance matrix generated by `dist()` and represents the relationship among the specimens as a network diagram. In order to use this script, a decision is required on a threshold for relatedness to be represented as link in the network, and on the layout used to create the diagram.

**Usage**

```r
gl.plot.network(
    D,  
    x = NULL,  
    method = "fr",  
    node.size = 3,  
    node.label = FALSE,  
    node.label.size = 0.7,  
    node.label.color = "black",  
    alpha = 0.005,  
    title = "Network based on genetic distance",  
    verbose = NULL
)
```

**Arguments**

- **D**: A distance or dissimilarity matrix generated by `dist()` or `gl.dist()` [required].
- **x**: A genlight object from which the D matrix was generated [default NULL].
- **method**: One of "fr", "kk" or "drl" [default "fr"].
- **node.size**: Size of the symbols for the network nodes [default 3].
- **node.label**: TRUE to display node labels [default FALSE].
- **node.label.size**: Size of the node labels [default 0.7].
- **node.label.color**: Color of the text of the node labels [default 'black'].
- **alpha**: Upper threshold to determine which links between nodes to display [default 0.005].
- **title**: Title for the plot [default "Network based on genetic distance"].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using `gl.set.verbosity`].
Details

The threshold for relatedness to be represented as a link in the network is specified as a quantile. Those relatedness measures above the quantile are plotted as links, those below the quantile are not. Often you are looking for relatedness outliers in comparison with the overall relatedness among individuals, so a very conservative quantile is used (e.g. 0.004), but ultimately, this decision is made as a matter of trial and error. One way to approach this trial and error is to try to achieve a sparse set of links between unrelated 'background' individuals so that the stronger links are preferentially shown.

There are several layouts from which to choose. The most popular are given as options in this script.

Colors of node symbols are those of the rainbow.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

D <- gl.grm(bandicoot.gl)
gl.plot.network(D, bandicoot.gl)

Description

This function takes a structure run object (output from gl.run.structure) and plots the typical structure bar plot that visualize the q matrix of a structure run.

Usage

```r
gl.plot.structure(
  sr,
  K = NULL,
  met_clumpp = "greedyLargeK",
  iter_clumpp = 100,
  clumpak = TRUE,
  plot_theme = NULL,
  colors_clusters = NULL,
  ind_name = TRUE,
)```
border_ind = 0.15,
plot.out = TRUE,
save2tmp = FALSE,
verbose = NULL
)

Arguments

sr Structure run object from gl.run.structure [required].
K The number for K of the q matrix that should be plotted. Needs to be within you simulated range of K's in your sr structure run object. If NULL, all the K's are plotted [default NULL].
met_clumpp The algorithm to use to infer the correct permutations. One of 'greedy' or 'greedyLargeK' or 'stephens' [default "greedyLargeK"].
iter_clumpp The number of iterations to use if running either 'greedy' 'greedyLargeK' [default 100].
clumpak Whether use the Clumpak method (see details) [default TRUE].
plot_theme Theme for the plot. See Details for options [default NULL].
colors_clusters A color palette for clusters (K) or a list with as many colors as there are clusters (K) [default NULL].
ind_name Whether to plot individual names [default TRUE].
border_ind The width of the border line between individuals [default 0.25].
plot.out Specify if plot is to be produced [default TRUE].
save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity]

Details

The function outputs a barplot which is the typical output of structure. For a Evanno plot use gl.evanno.

This function is based on the methods of CLUMPP and Clumpak as implemented in the R package starmie (https://github.com/sa-lee/starmie).

The Clumpak method identifies sets of highly similar runs among all the replicates of the same K. The method then separates the distinct groups of runs representing distinct modes in the space of possible solutions.

The CLUMPP method permutes the clusters output by independent runs of clustering programs such as structure, so that they match up as closely as possible.

This function averages the replicates within each mode identified by the Clumpak method.

Plots and table are saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in
• https://ggplot2.tidyverse.org/reference/ggtheme.html and
• https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value

List of Q-matrices

 # history=gl3$other$history[c(2,3)], verbose=1)
 # gl.print.history(bc.fil)

---

**Description**

Prints dartR reports saved in tempdir

**Usage**

gl.print.reports(print_report)

**Arguments**

- **print_report**  
  Number of report from gl.list.reports that is to be printed

**Value**

Prints reports that were saved in tempdir.
gl.propShared

Author(s)
Bernd Gruber & Luis Mijangos (bugs? Post to https://groups.google.com/d/forum/dartr)

See Also
gl.list.reports

Examples

```r
## Not run:
reports <- gl.print.reports(1)

## End(Not run)
```

---

gl.propShared  | Calculates a similarity (distance) matrix for individuals on the proportion of shared alleles

---

Description

This script calculates an individual based distance matrix. It uses an C++ implementation, so package Rcpp needs to be installed and it is therefore really fast (once it has compiled the function after the first run).

Usage

```r
gl.propShared(x)
```

Arguments

```r
x  Name of the genlight containing the SNP genotypes [required].
```

Author(s)

Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

Examples

```r
# takes some time at the first run of the function...
## Not run:
res <- gl.propShared(bandicoot.gl)
res[1:5,1:7] # show only a small part of the matrix

## End(Not run)
```
gl.random.snp  

Randomly changes the allocation of 0's and 2's in a genlight object

Description

This function samples randomly half of the SNPs and re-codes, in the sampled SNP's, 0's by 2's.

Usage

```r
gl.random.snp(x, plot.out = TRUE, save2tmp = FALSE, verbose = NULL)
```

Arguments

- **x**: Name of the genlight object containing the SNP data [required].
- **plot.out**: Specify if a plot is to be produced [default TRUE].
- **save2tmp**: If TRUE, saves any ggplots to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

DArT calls the most common allele as the reference allele. In a genlight object, homozygous for the reference allele are coded with a '0' and homozygous for the alternative allele are coded with a '2'. This causes some distortions in visuals from time to time.

If plot.out = TRUE, two smear plots (pre-randomisation and post-randomisation) are presented using a random subset of individuals (10) and loci (100) to provide an overview of the changes. Resultant ggplots are saved to the session’s temporary directory.

Value

Returns a genlight object with half of the loci re-coded.

Author(s)

Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

Examples

```r
res <- gl.random.snp(platypus.gl[1:10,1:10], verbose = 5)
```
gl.read.csv

Reads SNP data from a csv file into a genlight object

Description

This script takes SNP genotypes from a csv file, combines them with individual and locus metrics and creates a genlight object.

Usage

```r
gl.read.csv(
  filename,
  transpose = FALSE,
  ind.metafile = NULL,
  loc.metafile = NULL,
  verbose = NULL
)
```

Arguments

- `filename`: Name of the csv file containing the SNP genotypes [required].
- `transpose`: If TRUE, rows are loci and columns are individuals [default FALSE].
- `ind.metafile`: Name of the csv file containing the metrics for individuals [optional].
- `loc.metafile`: Name of the csv file containing the metrics for loci [optional].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

The SNP data need to be in one of two forms. SNPs can be coded 0 for homozygous reference, 2 for homozygous alternate, 1 for heterozygous, and NA for missing values; or the SNP data can be coded A/A, A/C, C/T, G/A etc, and -/- for missing data. In this format, the reference allele is the most frequent allele, as used by DArT. Other formats will throw an error.

The SNP data need to be individuals as rows, labeled, and loci as columns, also labeled. If the orientation is individuals as columns and loci by rows, then set transpose=TRUE.

The individual metrics need to be in a csv file, with headings, with a mandatory id column corresponding exactly to the individual identity labels provided with the SNP data and in the same order.

The locus metadata needs to be in a csv file with headings, with a mandatory column headed AlleleID corresponding exactly to the locus identity labels provided with the SNP data and in the same order.

Note that the locus metadata will be complemented by calculable statistics corresponding to those that would be provided by Diversity Arrays Technology (e.g. CallRate).
Value

A genlight object with the SNP data and associated metadata included.

Author(s)

Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

Examples

```r
csv_file <- system.file('extdata', 'platy_test.csv', package='dartR')
ind_metadata <- system.file('extdata', 'platy_ind.csv', package='dartR')
gl <- gl.read.csv(filename = csv_file, ind.metafile = ind_metadata)
```

Description

This function is a wrapper function that allows you to convert your DArT file into a genlight object in one step. In previous versions you had to use read.dart and then dart2genlight. In case you have individual metadata for each individual/sample you can specify as before in the dart2genlight command the file that combines the data.

Usage

```r
gl.read.dart(
  filename,
  ind.metafile = NULL,
  recalc = TRUE,
  mono.rm = FALSE,
  nas = "-",
  topskip = NULL,
  lastmetric = "RepAvg",
  covfilename = NULL,
  service_row = 1,
  plate_row = 3,
  probar = FALSE,
  verbose = NULL
)
```

Arguments

- **filename**: File containing the SNP data (csv file) [required].
- **ind.metafile**: File that contains additional information on individuals [required].
- **recalc**: Force the recalculation of locus metrics, in case individuals have been manually deleted from the input csv file [default TRUE].
mono.rm  Force the removal of monomorphic loci (including all NAs), in case individuals
have been manually deleted from the input csv file [default FALSE].

nas    A character specifying NAs [default '-'].

topskip A number specifying the number of rows to be skipped. If not provided the
number of rows to be skipped are 'guessed' by the number of rows with '*' at
the beginning [default NULL].

lastmetric Specifies the last non-genetic column (Default is 'RepAvg'). Be sure to check
if that is true, otherwise the number of individuals will not match. You can also
specify the last column by a number [default 'RepAvg'].

covfilename Use ind.metafile parameter [deprecated, NULL].

service_row The row number in which the information of the DArT service is contained
[default 1].

plate_row The row number in which the information of the plate location is contained
[default 3].

probar Show progress bar [default FALSE].

verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress
and results summary; 5, full report [default 2, or as set by gl.set.verbose()].

Details

The dartR genlight object can then be fed into a number of initial screening, export and export func-
tions provided by the package. For some of the functions it is necessary to have the metadata that
was provided from DArT. Please check the vignette for more information. Additional information
can also be found in the help documents for utils.read.dart.

Value

A genlight object that contains individual metrics [if data were provided] and locus metrics [from a
DArT report].

Author(s)

Custodian: Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

See Also

utils.read.dart

Examples

dartfile <- system.file('extdata','testset_SNPs_2Row.csv', package='dartR')
metadata <- system.file('extdata','testset_metadata.csv', package='dartR')
gl <- gl.read.dart(dartfile, ind.metafile = metadata, probar=TRUE)
**gl.read.silicodart**  
*Imports presence/absence data from SilicoDArT to genlight [age-genet] format (ploidy=1)*

### Description

DaRT provide the data as a matrix of entities (individual animals) across the top and attributes (P/A of sequenced fragment) down the side in a format that is unique to DArT. This program reads the data in to adegenet format for consistency with other programming activity. The script may require modification as DArT modify their data formats from time to time.

### Usage

```r
gl.read.silicodart(
  filename,
  ind.metafile = NULL,
  nas = "-",
  toskip = NULL,
  lastmetric = "Reproducibility",
  probar = TRUE,
  verbose = NULL
)
```

### Arguments

- `filename`  
  Name of csv file containing the SilicoDArT data [required].
- `ind.metafile`  
  Name of csv file containing metadata assigned to each entity (individual) [default NULL].
- `nas`  
  Missing data character [default `-`].
- `topskip`  
  Number of rows to skip before the header row (containing the specimen identities) [optional].
- `lastmetric`  
  Specifies the last non genetic column (Default is 'Reproducibility'). Be sure to check if that is true, otherwise the number of individuals will not match. You can also specify the last column by a number [default "Reproducibility"].
- `probar`  
  Show progress bar [default TRUE].
- `verbose`  
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, or as set by gl.set.verbose()].

### Details

`gl.read.silicodart()` opens the data file (csv comma delimited) and skips the first `n=toskip` lines. The script assumes that the next line contains the entity labels (specimen ids) followed immediately by the SNP data for the first locus.

It reads the presence/absence data into a matrix of 1s and 0s, and inputs the locus metadata and specimen metadata. The locus metadata comprises a series of columns of values for each locus.
including the essential columns of CloneID and the desirable variables Reproducibility and PIC. Refer to documentation provide by DArT for an explanation of these columns.

The specimen metadata provides the opportunity to reassign specimens to populations, and to add other data relevant to the specimen. The key variables are id (specimen identity which must be the same and in the same order as the SilicoDArT file, each unique), pop (population assignment), lat (latitude, optional) and lon (longitude, optional). id, pop, lat, lon are the column headers in the csv file. Other optional columns can be added.

The data matrix, locus names (forced to be unique), locus metadata, specimen names, specimen metadata are combined into a genind object. Refer to the documentation for {adegenet} for further details.

**Value**

An object of class genlight with ploidy set to 1, containing the presence/absence data, and locus and individual metadata.

**Author(s)**

Custodian: Bernd Gruber – Post to https://groups.google.com/d/forum/dartr

**See Also**

- `gl.read.dart`

**Examples**

```r
silicodartfile <- system.file("extdata","testset_SilicoDArT.csv", package="dartR")
metadata <- system.file("extdata",ind.metafile = "testset_metadata_silicodart.csv", package="dartR")
testset.gs <- gl.read.silicodart(filename = silicodartfile, ind.metafile = metadata)
```

---

**gl.read.vcf**

Converts a vcf file into a genlight object

**Description**

This function needs package vcfR, please install it. The converted genlight object does not have individual metrics. You need to add them 'manually' to the other$ind.metrics slot.

**Usage**

```r
gl.read.vcf(vcffile, verbose = NULL)
```

**Arguments**

- `vcffile` A vcf file (works only for diploid data) [required].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using `gl.set.verbosity`].
Value

A genlight object.

Author(s)

Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

Examples

```r
## Not run:
obj <- gl.read.vcf(system.file('extdata/test.vcf', package='dartR'))
## End(Not run)
```

---

**gl.reassign.pop**

Assigns an individual metric as pop in a genlight {adegenet} object

Description

Individuals are assigned to populations based on the individual/sample/specimen metrics file (csv) used with gl.read.dart().

One might want to define the population structure in accordance with another classification, such as using an individual metric (e.g. sex, male or female). This script discards the current population assignments and replaces them with new population assignments defined by a specified individual metric.

The script returns a genlight object with the new population assignments. Note that the original population assignments are lost.

Usage

```r
gl.reassign.pop(x, as.pop, verbose = NULL)
```

Arguments

- `x` Name of the genlight object containing SNP genotypes [required].
- `as.pop` Specify the name of the individual metric to set as the pop variable [required].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

A genlight object with the reassigned populations.

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr
gl.recalc.metrics
Recalculates locus metrics when individuals or populations are deleted from a genlight adegenet object

Description
When individuals or populations are deleted from a genlight object, the locus metrics no longer apply. For example, the Call Rate may be different considering the subset of individuals, compared with the full set. This script recalculates those affected locus metrics, namely, avgPIC, CallRate, freqHets, freqHomRef, freqHomSnp, OneRatioRef, OneRatioSnp, PICRef and PICSnp. Metrics that remain unaltered are RepAvg and TrimmedSeq as they are unaffected by the removal of individuals.

Usage
gl.recalc.metrics(x, mono.rm = FALSE, verbose = NULL)

Arguments
x
Name of the genlight object containing SNP genotypes [required].
mono.rm
If TRUE, removes monomorphic loci [default FALSE].
verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details
The script optionally removes resultant monomorphic loci or loci with all values missing and deletes them (using gl.filter.monomorphs.r).
The script returns a genlight object with the recalculated locus metadata.

Value
A genlight object with the recalculated locus metadata.

Author(s)
Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)
See Also

`gl.filter.monomorphs`

Examples

```r
gl <- gl.recalc.metrics(testset.gl, verbose=2)
```

---

**gl.recode.ind**

Recodes individual (=specimen = sample) labels in a genlight object

Description

This script recodes individual labels and/or deletes individuals from a DaRT genlight SNP file based on a lookup table provided as a csv file.

Usage

```r
gl.recode.ind(x, ind.recode, recalc = FALSE, mono.rm = FALSE, verbose = NULL)
```

Arguments

- `x`: Name of the genlight object containing SNP genotypes [required].
- `ind.recode`: Name of the csv file containing the individual relabelling [required].
- `recalc`: If TRUE, recalculate the locus metadata statistics if any individuals are deleted in the filtering [default FALSE].
- `mono.rm`: If TRUE, remove monomorphic loci [default FALSE].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`].

Details

Renaming individuals may be required when there have been errors in labelling arising in the process from sample to DaRT files. There may be occasions where renaming individuals is required for preparation of figures. When caution needs to be exercised because of the potential for breaking the 'chain of evidence' associated with the samples, recoding individuals using a recode table (csv) can provide a clear record of the changes.

The script, having deleted individuals, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using `gl.filter.monomorphs.r`). The script also optionally recalculates statistics made incorrect by the deletion of individuals from the dataset.

The script returns a genlight object with the new individual labels, the monomorphic loci optionally removed and the optionally recalculated locus metadata.

Value

A genlight or genind object with the recoded and reduced data.
gl.recode.pop

Author(s)
Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

See Also

gl.filter.monomorphs for filtering monomorphs, gl.recalc.metrics for recalculating locus metrics, gl.recode.pop for recoding populations

Examples

```r
file <- system.file('extdata','testset_ind_recode.csv', package='dartR')
gl <- gl.recode.ind(testset.gl, ind.recode=file, verbose=3)
```

---

gl.recode.pop  

*Recodes population assignments in a genlight object*

Description

This script recodes population assignments and/or deletes populations from a DaRT genlight SNP file based on information provided in a csv population recode file.

Usage

```r
gl.recode.pop(x, pop.recode, recalc = FALSE, mono.rm = FALSE, verbose = NULL)
```

Arguments

- `x` Name of the genlight object containing the SNP data [required].
- `pop.recode` Name of the csv file containing the population reassignments [required].
- `recalc` Recalculate the locus metadata statistics if any individuals are deleted in the filtering [default FALSE].
- `mono.rm` Remove monomorphic loci [default FALSE].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

Individuals are assigned to populations based on the specimen metadata data file (csv) used with gl.read.dart(). Recoding can be used to amalgamate populations or to selectively delete or retain populations.

The population recode file contains a list of populations in the genlight object as the first column of the csv file, and the new population assignments in the second column of the csv file. The keyword Delete used as a new population assignment will result in the associated specimen being dropped from the dataset.

The script, having deleted populations, optionally identifies resultant monomorphic loci or loci with all values missing and deletes them (using gl.filter.monomorphs.r). The script also optionally recalculates the locus metadata as appropriate.
Value

A genlight object with the recoded and reduced data.

```

---

gl.rename.pop  

Renames a population in a genlight object

Description

Individuals are assigned to populations based on the specimen metadata data file (csv) used with gl.read.dart().

This script renames a nominated population.

The script returns a genlight object with the new population name.

Usage

```r
gl.rename.pop(x, old = NULL, new = NULL, verbose = NULL)
```

Arguments

- `x`  
  Name of the genlight object containing SNP genotypes [required].

- `old`  
  Name of population to be changed [required].

- `new`  
  New name for the population [required].

- `verbose`  
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

A genlight object with the new population name.
Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

```r
gl <- gl.rename.pop(testset.gl, old='EmsubRopeMata', new='Outgroup')
```

---

**gl.report.bases**

Reports summary of base pair frequencies

Description

This script calculates the frequencies of the four DNA nucleotide bases: adenine (A), cytosine (C), guanine (G) and thymine (T), and the frequency of transitions (Ts) and transversions (Tv) in a DArT genlight object.

Usage

```r
gl.report.bases(
  x,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- **x**: Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].
- **plot.out**: If TRUE, histograms of base composition are produced [default TRUE].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: List of two color names for the borders and fill of the plots [default two_colors].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (temppdir) [default FALSE]
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity]
Details

The script checks first if trimmed sequences are included in the locus metadata (@other$loc.metrics$TrimmedSequence), and if so, tallies up the numbers of A, T, G and C bases. Only the reference state at the SNP locus is counted. Counts of transitions (Ts) and transversions (Tv) assume that there is no directionality, that is C->T is the same as T->C, because the reference state is arbitrary.

For presence/absence data (SilicoDArT), it is not possible to count transversions or transitions or transversions/transitions ratio because the SNP data is not available, only a single sequence tag.

Examples of other themes that can be used can be consulted in

- https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value

The unchanged genlight object

out <- gl.report.bases(testset.gl)

# Tag P/A data
out <- gl.report.bases(testset.gs)
```

---

**gl.report.callrate**

Reports summary of Call Rate for loci or individuals

Description

SNP datasets generated by DArT have missing values primarily arising from failure to call a SNP because of a mutation at one or both of the restriction enzyme recognition sites. P/A datasets (SilicoDArT) have missing values because it was not possible to call whether a sequence tag was amplified or not. This function tabulates the number of missing values as quantiles.
Usage

gl.report.callrate(
  x,
  method = "loc",
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  bins = 50,
  save2tmp = FALSE,
  verbose = NULL
)

Arguments

x
Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].

method
Specify the type of report by locus (method='loc') or individual (method='ind') [default 'loc'].

plot.out
Specify if plot is to be produced [default TRUE].

plot_theme
User specified theme [default theme_dartR()].

plot_colors
Vector with two color names for the borders and fill [default two_colors].

bins
Number of bins to display in histograms [default 25].

save2tmp
If TRUE, saves any ggplots and listings to the session temporary directory (tmpdir) [default FALSE].

verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

This function expects a genlight object, containing either SNP data or SilicoDArT (=presence/absence data).

Callrate is summarized by locus or by individual to allow sensible decisions on thresholds for filtering taking into consideration consequential loss of data. The summary is in the form of a tabulation and plots.

Plot themes can be obtained from:

- https://ggplot2.tidyverse.org/reference/ggtheme.html and
- https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Resultant ggplots and the tabulation are saved to the session’s temporary directory.

Value

Returns unaltered genlight object
gl.report.diversity

Calculates diversity indexes for SNPs

Description

This script takes a genlight object and calculates alpha and beta diversity for q = 0:2. Formulas are taken from Sherwin et al. 2017. The paper describes nicely the relationship between the different q levels and how they relate to population genetic processes such as dispersal and selection.

Usage

```r
gl.report.diversity(
  x,
  plot.out = TRUE,
  pbar = TRUE,
  table = "DH",
  plot_theme = theme_dartR(),
  plot_colors = discrete_palette,
  save2tmp = FALSE,
  verbose = NULL
)
```
Arguments

- **x**: Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].
- **plot.out**: Specify if plot is to be produced [default TRUE].
- **pbar**: Report on progress. Silent if set to FALSE [default TRUE].
- **table**: Prints a tabular output to the console either 'D'=D values, or 'H'=H values or 'DH','HD'=both or 'N'=no table. [default 'DH'].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: A color palette or a list with as many colors as there are populations in the dataset [default discrete_palette].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

For all indexes, the entropies (H) and corresponding effective numbers, i.e. Hill numbers (D), which reflect the number of needed entities to get the observed values, are calculated. In a nutshell, the alpha indexes between the different q-values should be similar if there is no deviation from expected allele frequencies and occurrences (e.g. all loci in HWE & equilibrium). If there is a deviation of an index, this links to a process causing it, such as dispersal, selection or strong drift. For a detailed explanation of all the indexes, we recommend resorting to the literature provided below. Confidence intervals are +/- 1 standard deviation.

Function’s output

Plots are saved to the temporal directory (tempdir) and can be accessed with the function `gl.print.reports` and listed with the function `gl.list.reports`. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in

- https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value

A list of entropy indexes for each level of q and equivalent numbers for alpha and beta diversity.

---

`gl.report.hamming`  
Calculates the pairwise Hamming distance between DArT trimmed DNA sequences

---

Description

Hamming distance is calculated as the number of base differences between two sequences which can be expressed as a count or a proportion. Typically, it is calculated between two sequences of equal length. In the context of DArT trimmed sequences, which differ in length but which are anchored to the left by the restriction enzyme recognition sequence, it is sensible to compare the two trimmed sequences starting from immediately after the common recognition sequence and terminating at the last base of the shorter sequence.

Usage

```r
gl.report.hamming(
  x,  
  rs = 5,  
  threshold = 3,  
  taglength = 69,  
  plot.out = TRUE,  
  plot_theme = theme_dartR(),  
  plot_colors = two_colors,  
  probar = FALSE,  
  save2tmp = FALSE,  
  verbose = NULL  
)
```

Arguments

- `x` Name of the genlight object containing the SNP data [required].
- `rs` Number of bases in the restriction enzyme recognition sequence [default 5].
- `threshold` Minimum acceptable base pair difference for display on the boxplot and histogram [default 3].
### gl.report.hamming

</tr>
</tbody>
</table>

### Details

The function `gl.filter.hamming` will filter out one of two loci if their Hamming distance is less than a specified percentage.

Hamming distance can be computed by exploiting the fact that the dot product of two binary vectors x and (1-y) counts the corresponding elements that are different between x and y. This approach can also be used for vectors that contain more than two possible values at each position (e.g. A, C, T or G).

If a pair of DNA sequences are of differing length, the longer is truncated.

The algorithm is that of Johann de Jong [https://johanndejong.wordpress.com/2015/10/02/faster-hamming-distance-in-r-2/](https://johanndejong.wordpress.com/2015/10/02/faster-hamming-distance-in-r-2/) as implemented in `utils.hamming`.

Plots and table are saved to the session’s temporary directory (tempdir).

Examples of other themes that can be used can be consulted in:

gl.report.heterozygosity

Reports observed, expected and unbiased heterozygosities and FIS (inbreeding coefficient) by population or by individual from SNP data

Description

Calculates the observed, expected and unbiased expected (i.e. corrected for sample size) heterozygosities and FIS (inbreeding coefficient) for each population or the observed heterozygosity for each individual in a genlight object.

Usage

gl.report.heterozygosity(
  x,
  method = "pop",
  n.invariant = 0,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors_pop = discrete_palette,
  plot_colors_ind = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)

Arguments

x Name of the genlight object containing the SNP [required].
method Calculate heterozygosity by population (method='pop') or by individual (method='ind') [default 'pop'].
n.invariant An estimate of the number of invariant sequence tags used to adjust the heterozygosity rate [default 0].
plot.out Specify if plot is to be produced [default TRUE].
plot_theme Theme for the plot. See Details for options [default theme_dartR()].
plot_colors_pop A color palette for population plots or a list with as many colors as there are populations in the dataset [default discrete_palette].
plot_colors_ind List of two color names for the borders and fill of the plot by individual [default two_colors].
save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose Verbose: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].
Details

Observed heterozygosity for a population takes the proportion of heterozygous loci for each individual then averages over the individuals in that population. The calculations take into account missing values.

Expected heterozygosity for a population takes the expected proportion of heterozygotes, that is, expected under Hardy-Weinberg equilibrium, for each locus, then averages this across the loci for an average estimate for the population.

Observed heterozygosity for individuals is calculated as the proportion of loci that are heterozygous for that individual.

Finally, the loci that are invariant across all individuals in the dataset (that is, across populations), is typically unknown. This can render estimates of heterozygosity analysis specific, and so it is not valid to compare such estimates across species or even across different analyses. This is a similar problem faced by microsatellites. If you have an estimate of the number of invariant sequence tags (loci) in your data, such as provided by gl.report.secondaries, you can specify it with the n.invariant parameter to standardize your estimates of heterozygosity.

NOTE: It is important to realise that estimation of adjusted heterozygosity requires that secondaries not to be removed.

Heterozygosities and FIS (inbreeding coefficient) are calculated by locus within each population using the following equations:

- Observed heterozygosity (Ho) = number of homozygotes / n_Ind, where n_Ind is the number of individuals without missing data.
- Observed heterozygosity adjusted (Ho.adj) <- Ho * n_Loc / (n_Loc + n.invariant), where n_Loc is the number of loci that do not have all missing data and n.invariant is an estimate of the number of invariant loci to adjust heterozygosity.
- Expected heterozygosity (He) = 1 - (p^2 + q^2), where p is the frequency of the reference allele and q is the frequency of the alternative allele.
- Expected heterozygosity adjusted (He.adj) = He * n_Loc / (n_Loc + n.invariant)
- Unbiased expected heterozygosity (uHe) = He * (2 * n_Ind / (2 * n_Ind - 1))
- Inbreeding coefficient (FIS) = 1 - (mean(Ho) / mean(uHe))

Function's output

Output for method='pop' is an ordered barchart of observed heterozygosity, expected heterozygosity and FIS (Inbreeding coefficient) across populations together with a table of mean observed and expected heterozygosities and FIS by population and their respective standard deviations (SD).

Output for method='ind' is a histogram and a boxplot of heterozygosity across individuals.

Plots and table are saved to the session temporary directory (tempdir)

Examples of other themes that can be used can be consulted in

df <- gl.report.heterozygosity(platypus.gl)
df <- gl.report.heterozygosity(platypus.gl, method='ind')
n.inv <- gl.report.secondaries(platypus.gl)
gl.report.heterozygosity(platypus.gl, n.invariant = n.inv[7, 2])
```

---

**gl.report.hwe**  
*Reports departure from Hardy-Weinberg proportions*

**Description**

Calculates the probabilities of agreement with H-W proportions based on observed frequencies of reference homozygotes, heterozygotes and alternate homozygotes.

**Usage**

```r
gl.report.hwe(
  x,
  subset = "each",
  method_sig = "Exact",
  multi_comp = FALSE,
  multi_comp_method = "BY",
  alpha_val = 0.05,
  pvalue_type = "midp",
  cc_val = 0.5,
  sig_only = TRUE,
  min_sample_size = 5,
  plot.out = TRUE,
  plot_colors = two_colors_contrast,
  max_plots = 4,
  save2tmp = FALSE,
  verbose = NULL
)
```
Arguments

- **x**: Name of the genlight object containing the SNP data [required].
- **subset**: Way to group individuals to perform H-W tests. Either a vector with population names, 'each', 'all' (see details) [default 'each'].
- **method_sig**: Method for determining statistical significance: 'ChiSquare' or 'Exact' [default 'Exact'].
- **multi_comp**: Whether to adjust p-values for multiple comparisons [default FALSE].
- **multi_comp_method**: Method to adjust p-values for multiple comparisons: 'holm', 'hochberg', 'hommel', 'bonferroni', 'BH', 'BY', 'fdr' (see details) [default 'fdr'].
- **alpha_val**: Level of significance for testing [default 0.05].
- **pvalue_type**: Type of p-value to be used in the Exact method. Either 'dost','selome','midp' (see details) [default 'midp'].
- **cc_val**: The continuity correction applied to the ChiSquare test [default 0.5].
- **sig_only**: Whether the returned table should include loci with a significant departure from Hardy-Weinberg proportions [default TRUE].
- **min_sample_size**: Minimum number of individuals per population in which perform H-W tests [default 5].
- **plot.out**: If TRUE, will produce Ternary Plot(s) [default TRUE].
- **plot_colors**: Vector with two color names for the significant and not-significant loci [default two_colors_contrast].
- **max_plots**: Maximum number of plots to print per page [default 4].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

There are several factors that can cause deviations from Hardy-Weinberg proportions including: mutation, finite population size, selection, population structure, age structure, assortative mating, sex linkage, nonrandom sampling and genotyping errors. Therefore, testing for Hardy-Weinberg proportions should be a process that involves a careful evaluation of the results, a good place to start is Waples (2015).

Note that tests for H-W proportions are only valid if there is no population substructure (assuming random mating) and have sufficient power only when there is sufficient sample size (n individuals > 15).

Populations can be defined in three ways:

- Merging all populations in the dataset using subset = 'all'.
- Within each population separately using: subset = 'each'.
- Within selected populations using for example: subset = c('pop1','pop2').
Two different statistical methods to test for deviations from Hardy Weinberg proportions:

- The classical chi-square test (method.sig='ChiSquare') based on the function HWChisq of the R package HardyWeinberg. By default a continuity correction is applied (cc_val=0.5). The continuity correction can be turned off (by specifying cc_val=0), for example in cases of extreme allele frequencies in which the continuity correction can lead to excessive type 1 error rates.

- The exact test (method.sig='Exact') based on the exact calculations contained in the function HWExactStats of the R package HardyWeinberg, and described in Wigginton et al. (2005). The exact test is recommended in most cases (Wigginton et al., 2005). Three different methods to estimate p-values (pvalue_type) in the Exact test can be used:
  - 'dost' p-value is computed as twice the tail area of a one-sided test.
  - 'selome' p-value is computed as the sum of the probabilities of all samples less or equally likely as the current sample.
  - 'midp', p-value is computed as half the probability of the current sample + the probabilities of all samples that are more extreme.

The standard exact p-value is overly conservative, in particular for small minor allele frequencies. The mid p-value ameliorates this problem by bringing the rejection rate closer to the nominal level, at the price of occasionally exceeding the nominal level (Graffelman & Moreno, 2013).

Correction for multiple tests can be applied using the following methods based on the function p.adjust:

- 'holm' is also known as the sequential Bonferroni technique (Rice, 1989). This method has a greater statistical power than the standard Bonferroni test, however this method becomes very stringent when many tests are performed and many real deviations from the null hypothesis can go undetected (Waples, 2015).
- 'hommel' based on Hommel, 1988. This method is more powerful than Hochberg’s, but the difference is usually small.
- 'bonferroni' in which p-values are multiplied by the number of tests. This method is very stringent and therefore has reduced power to detect multiple departures from the null hypothesis.

The first four methods are designed to give strong control of the family-wise error rate. The last two methods control the false discovery rate (FDR), the expected proportion of false discoveries among the rejected hypotheses. The false discovery rate is a less stringent condition than the family-wise error rate, so these methods are more powerful than the others, especially when number of tests is large. The number of tests on which the adjustment for multiple comparisons is the number of populations times the number of loci.

**Ternary plots**

Ternary plots can be used to visualise patterns of H-W proportions (plot.out = TRUE). P-values and the statistical (non)significance of a large number of bi-allelic markers can be inferred from
their position in a ternary plot. See Graffelman & Morales-Camarena (2008) for further details. Ternary plots are based on the function HWTeraryPlot from the package HardyWeinberg. Each vertex of the Ternary plot represents one of the three possible genotypes for SNP data: homozygous for the reference allele (AA), heterozygous (AB) and homozygous for the alternative allele (BB). Loci deviating significantly from Hardy-Weinberg proportions after correction for multiple tests are shown in pink. The blue parabola represents Hardy-Weinberg equilibrium, and the area between green lines represents the acceptance region.

For these plots to work it is necessary to install the package ggtern.

**Value**

A dataframe containing loci, counts of reference SNP homozygotes, heterozygotes and alternate SNP homozygotes; probability of departure from H-W proportions, per locus significance with and without correction for multiple comparisons and the number of population where the same locus is significantly out of hwe.

**See Also**

- gl.filter.hwe
  Other filters/filter reports: gl.filter.hwe()

**Examples**

- gl.report.hwe(x = bandicoot.gl)
Calculates pairwise population based Linkage Disequilibrium across all loci using the specified number of cores

Description

This function is implemented in a parallel fashion to speed up the process. There is also the ability to restart the function if crashed by specifying the chunk file names or restarting the function exactly in the same way as in the first run. This is implemented because sometimes, due to connectivity loss between cores, the function may crash half way. Before running the function, it is advisable to use the function `gl.filter.allna` to remove loci with all missing data.

Usage

```r
gl.report.ld(
  x,
  name = NULL,
  save = TRUE,
  outpath = tempdir(),
  nchunks = 2,
  ncores = 1,
  chunkname = NULL,
  probar = FALSE,
  verbose = NULL
)
```

Arguments

- **x**: A genlight or genind object created (genlight objects are internally converted via `gl2gi` to genind) [required].
- **name**: Character string for rdata file. If not given genind object name is used [default `NULL`].
- **save**: Switch if results are saved in a file [default `TRUE`].
- **outpath**: Folder where chunks and results are saved (if save=TRUE) [default `tempdir()`].
- **nchunks**: How many subchunks will be used (the less the faster, but if the routine crashes more bits are lost) [default `2`].
- **ncores**: How many cores should be used [default `1`].
- **chunkname**: The name of the chunks for saving [default `NULL`].
- **probar**: if TRUE, a progress bar is displayed for long loops [default = `TRUE`].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default `2` or as specified using `gl.set.verbosity`].
**gl.report.ld.map**

**Value**

Returns calculation of pairwise LD across all loci between subpopulations. This functions uses if specified many cores on your computer to speed up. And if save is used can restart (if save=TRUE is used) with the same command starting where it crashed. The final output is a data frame that holds all statistics of pairwise LD between loci. (See ?LD in package genetics for details).

**Author(s)**

Bernd Gruber (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

---

**Description**

This function calculates pairwise linkage disequilibrium (LD) within each chromosome and by population using the function ld (package snpStats).

This function requires that SNPs to be mapped to a reference genome and the information for SNP’s position must be stored in the genlight accessor position” and the SNP’s chromosome name in the accessor chromosome.

**Usage**

```
gl.report.ld.map(
  x,
  ld_max_pairwise = 1e+06,
  ld_resolution = 10000,
  maf = 0.05,
  ld_stat = "R.squared",
  stat_keep = "AvgPIC",
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)
```

**Arguments**

- **x**  
  Name of the genlight object containing the SNP data [required].
- **ld_max_pairwise**  
  Maximum distance in number of base pairs at which LD should be calculated [default 1000000].
- **ld_resolution**  
  Resolution at which LD should be reported in number of base pairs [default 10000]
maf Minor allele frequency threshold to filter out loci [default 0.05].

ld_stat The LD measure to be calculated: "LLR", "OR", "Q", "Covar", "D.prime", "R.squared", and "R" [default "R.squared"].

stat_keep Name of the column from the slot loc.metrics to be used to choose SNP to be kept [default "AvgPIC"].

plot.out Specify if plot is to be produced [default TRUE].

plot_theme User specified theme [default theme_dartR()].

plot_colors Vector with two color names for the borders and fill [default two_colors].

save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].

verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

This function reports pairwise LD of those SNPs in which the LD measure is > 0 in all the populations. The LD plot shows the pairwise LD measure against distance in number of base pairs pooled over all the chromosomes and a red line representing the threshold (R.squared = 0.2) that is commonly used to imply that two loci are unlinked (Delourme et al., 2013; Li et al., 2014).

Value

A dataframe with information for each SNP pair in LD.

Examples

```r
## Not run:
x <- platypus.gl
x$position <- x$other$loc.metrics$ChromPos_Platypus_Chrom_NCBIv1
x$chromosome <- x$other$loc.metrics$Chrom_Platypus_Chrom_NCBIv1
gl.report.ld.map(x, ld_resolution = 100000)
```

## End(Not run)
gl.report.locmetric

Reports summary of the slot $other$loc.metrics

Description

This script uses any field with numeric values stored in $other$loc.metrics to produce summary statistics (mean, minimum, average, quantiles), histograms and boxplots to assist the decision of choosing thresholds for the filter function gl.filter.locmetric.

Usage

```r
gl.report.locmetric(
  x,
  metric,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- `x` Name of the genlight object containing the SNP or presence/absence (Silico-DArT) data [required].
- `metric` Name of the metric to be used for filtering [required].
- `plot.out` Specify if plot is to be produced [default TRUE].
- `plot_theme` Theme for the plot. See Details for options [default theme_dartR()].
- `plot_colors` List of two color names for the borders and fill of the plots [default two_colors].
- `save2tmp` If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

The function gl.filter.locmetric will filter out the loci with a locmetric value below a specified threshold.

The fields that are included in dartR, and a short description, are found below. Optionally, the user can also set his/her own field by adding a vector into $other$loc.metrics as shown in the example. You can check the names of all available loc.metrics via: names(gl$other$loc.metrics).

- **SnpPosition** - position (zero is position 1) in the sequence tag of the defined SNP variant base.
- **CallRate** - proportion of samples for which the genotype call is non-missing (that is, not '-' ).
• OneRatioRef - proportion of samples for which the genotype score is 0.
• OneRatioSnp - proportion of samples for which the genotype score is 2.
• FreqHomRef - proportion of samples homozygous for the Reference allele.
• FreqHomSnp - proportion of samples homozygous for the Alternate (SNP) allele.
• FreqHets - proportion of samples which score as heterozygous, that is, scored as 1.
• PICRef - polymorphism information content (PIC) for the Reference allele.
• PICSnp - polymorphism information content (PIC) for the SNP.
• AvgPIC - average of the polymorphism information content (PIC) of the reference and SNP alleles.
• AvgCountRef - sum of the tag read counts for all samples, divided by the number of samples with non-zero tag read counts, for the Reference allele row.
• AvgCountSnp - sum of the tag read counts for all samples, divided by the number of samples with non-zero tag read counts, for the Alternate (SNP) allele row.
• RepAvg - proportion of technical replicate assay pairs for which the marker score is consistent.
• rdepth - read depth.

Function’s output
The minimum, maximum, mean and a tabulation of quantiles of the locmetric values against thresholds rate are provided. Output also includes a boxplot and a histogram.

Quantiles are partitions of a finite set of values into q subsets of (nearly) equal sizes. In this function q = 20. Quantiles are useful measures because they are less susceptible to long-tailed distributions and outliers.

Plots and table were saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in:

• https://ggplot2.tidyverse.org/reference/ggtheme.html and
• https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value
An unaltered genlight object.

---

**gl.report.maf**  
*Reports minor allele frequency (MAF) for each locus in a SNP dataset*

**Description**

This script provides summary histograms of MAF for each population in the dataset and an overall histogram to assist the decision of choosing thresholds for the filter function `gl.filter.maf`.

**Usage**

```r
gl.report.maf(  
  x,  
  maf.limit = 0.5,  
  ind.limit = 5,  
  plot.out = TRUE,  
  plot_theme = theme_dartR(),  
  plot_colors_pop = discrete_palette,  
  plot_colors_all = two_colors,  
  bins = 25,  
  save2tmp = FALSE,  
  verbose = NULL  
)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data [required].
- `maf.limit` Show histograms MAF range <= maf.limit [default 0.5].
- `ind.limit` Show histograms only for populations of size greater than ind.limit [default 5].
- `plot.out` Specify if plot is to be produced [default TRUE].
- `plot_theme` Theme for the plot. See Details for options [default theme_dartR()].
- `plot_colors_pop` A color palette for population plots [default discrete_palette].
plot_colors_all
List of two color names for the borders and fill of the overall plot [default two_colors].

bins
Number of bins to display in histograms [default 25].

save2tmp
If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].

verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details
The function gl.filter.maf will filter out the loci with MAF below a specified threshold.

Function’s output
The minimum, maximum, mean and a tabulation of MAF quantiles against thresholds rate are provided. Output also includes a boxplot and a histogram.

This function reports the MAF for each of several quantiles. Quantiles are partitions of a finite set of values into q subsets of (nearly) equal sizes. In this function q = 20. Quantiles are useful measures because they are less susceptible to long-tailed distributions and outliers.

Plots and table are saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in

• https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value
An unaltered genlight object

Author(s)
Custodian: Arthur Georges (Post to https://groups.google.com/d/forum/dartr)

See Also
gl.filter.maf, gl.list.reports, gl.print.reports

Examples
gl <- gl.report.maf(testset.gl)
Description

This script reports the number of monomorphic loci and those with all NAs in a genlight (adegenet) object.

Usage

```r
gl.report.monomorphs(x, verbose = NULL)
```

Arguments

- `x`: Name of the input genlight object [required].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

A DArT dataset will not have monomorphic loci, but they can arise, along with loci that are scored all NA, when populations or individuals are deleted. Retaining monomorphic loci unnecessarily increases the size of the dataset and will affect some calculations.

Note that for SNP data, NAs likely represent null alleles; in tag presence/absence data, NAs represent missing values (presence/absence could not be reliably scored).

Value

An unaltered genlight object

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

See Also

- `gl.filter.monomorphs`

Examples

```r
# SNP data
gl.report.monomorphs(testset.gl)
# SilicoDArT data
gl.report.monomorphs(testset.gs)
```
gl.report.overshoot  
*Reports loci for which the SNP has been trimmed from the sequence tag along with the adaptor*

**Description**

This function checks the position of the SNP within the trimmed sequence tag and identifies those for which the SNP position is outside the trimmed sequence tag. This can happen, rarely, when the sequence containing the SNP resembles the adaptor.

**Usage**

```r
gl.report.overshoot(x, save2tmp = FALSE, verbose = NULL)
```

**Arguments**

- `x`: Name of the genlight object [required].
- `save2tmp`: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

**Details**

The SNP genotype can still be used in most analyses, but functions like `gl2fasta()` will present challenges if the SNP has been trimmed from the sequence tag.

Resultant ggplot(s) and the tabulation(s) are saved to the session’s temporary directory.

**Value**

An unaltered genlight object

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**See Also**

- `gl.filter.overshoot`

**Examples**

```r
gl.report.overshoot(testset.gl)
```
Reports private alleles (and fixed alleles) per pair of populations

Description

This function reports private alleles in one population compared with a second population, for all populations taken pairwise. It also reports a count of fixed allelic differences and the mean absolute allele frequency differences (AFD) between pairs of populations.

Usage

```r
gl.report.pa(
  x,
  x2 = NULL,
  method = "pairwise",
  plot.out = TRUE,
  font_plot = 14,
  map.interactive = FALSE,
  palette_discrete = discrete_palette,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- **x** Name of the genlight object containing the SNP data [required].
- **x2** If two separate genlight objects are to be compared this can be provided here, but they must have the same number of SNPs [default NULL].
- **method** Method to calculate private alleles: 'pairwise' comparison or compare each population against the rest 'one2rest' [default 'pairwise'].
- **plot.out** Specify if Sankey plot is to be produced [default TRUE].
- **font_plot** Numeric font size in pixels for the node text labels [default 14].
- **map.interactive** Specify whether an interactive map showing private alleles between populations is to be produced [default FALSE].
- **palette_discrete** A discrete palette for the color of populations or a list with as many colors as there are populations in the dataset [default discrete_palette].
- **save2tmp** If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose** Verbosity: 0, silent, fatal errors only; 1, flag function begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
Details

Note that the number of paired alleles between two populations is not a symmetric dissimilarity measure.

If no x2 is provided, the function uses the pop(gl) hierarchy to determine pairs of populations, otherwise it runs a single comparison between x and x2.

**Hint**: in case you want to run comparisons between individuals (assuming individual names are unique), you can simply redefine your population names with your individual names, as below:

```r
callNames(gl) <- indNames(gl)
```

**Definition of fixed and private alleles**

The table below shows the possible cases of allele frequencies between two populations (0 = homozygote for Allele 1, x = both Alleles are present, 1 = homozygote for Allele 2).

- **p**: cases where there is a private allele in pop1 compared to pop2 (but not vice versa)
- **f**: cases where there is a fixed allele in pop1 (and pop2, as those cases are symmetric)

<table>
<thead>
<tr>
<th></th>
<th>0</th>
<th>x</th>
<th>1</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>pop1</strong></td>
<td></td>
<td>p</td>
<td>p,f</td>
</tr>
<tr>
<td><strong>pop2</strong></td>
<td>x</td>
<td></td>
<td></td>
</tr>
<tr>
<td></td>
<td>1</td>
<td>p,f</td>
<td></td>
</tr>
</tbody>
</table>

The absolute allele frequency difference (AFD) in this function is a simple differentiation metric displaying intuitive properties which provides a valuable alternative to FST. For details about its properties and how it is calculated see Berner (2019).

In this function a Sankey Diagram is used to visualize patterns of private alleles between populations. This diagram allows to display flows (private alleles) between nodes (populations). Their links are represented with arcs that have a width proportional to the importance of the flow (number of private alleles).

If save2temp=TRUE, resultant plot(s) and the tabulation(s) are saved to the session’s temporary directory.

**Value**

A data.frame. Each row shows, for each pair of populations the number of individuals in each population, the number of loci with fixed differences (same for both populations) in pop1 (compared to pop2) and vice versa. Same for private alleles and finally the absolute mean allele frequency difference between loci (AFD).

Examples

```r
out <- gl.report.pa(testset.gl[1:20,])
```

---

### gl.report.parent.offspring

*Identifies putative parent offspring within a population*

**Description**

This script examines the frequency of pedigree inconsistent loci, that is, those loci that are homozygotes in the parent for the reference allele, and homozygous in the offspring for the alternate allele. This condition is not consistent with any pedigree, regardless of the (unknown) genotype of the other parent. The pedigree inconsistent loci are counted as an indication of whether or not it is reasonable to propose the two individuals are in a parent-offspring relationship.

**Usage**

```r
gl.report.parent.offspring(
  x, 
  min.rdepth = 12, 
  min.reproducibility = 1, 
  range = 1.5, 
  plot.out = TRUE, 
  plot_theme = theme_dartR(), 
  plot_colors = two_colors, 
  save2tmp = FALSE, 
  verbose = NULL
)
```

**Arguments**

- `x` Name of the genlight object containing the SNP genotypes [required].
- `min.rdepth` Minimum read depth to include in analysis [default 12].
- `min.reproducibility` Minimum reproducibility to include in analysis [default 1].
range   Specifies the range to extend beyond the interquartile range for delimiting outliers [default 1.5 interquartile ranges].
plot.out  Creates a plot that shows the sex linked markers [default TRUE].
plot_theme  Theme for the plot. See Details for options [default theme_dartR()].
plot_colors  List of two color names for the borders and fill of the plots [default two_colors].
save2tmp  If TRUE, saves any ggplots and listings to the session temporary directory (tmpdir) [default FALSE].
verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details
If two individuals are in a parent offspring relationship, the true number of pedigree inconsistent loci should be zero, but SNP calling is not infallible. Some loci will be miss-called. The problem thus becomes one of determining if the two focal individuals have a count of pedigree inconsistent loci less than would be expected of typical unrelated individuals. There are some quite sophisticated software packages available to formally apply likelihoods to the decision, but we use a simple outlier comparison.

To reduce the frequency of miss-calls, and so emphasize the difference between true parent-offspring pairs and unrelated pairs, the data can be filtered on read depth.

Typically minimum read depth is set to 5x, but you can examine the distribution of read depths with the function gl.report.rdepth and push this up with an acceptable loss of loci. 12x might be a good minimum for this particular analysis. It is sensible also to push the minimum reproducibility up to 1, if that does not result in an unacceptable loss of loci. Reproducibility is stored in the slot @other$loc.metrics$RepAvg and is defined as the proportion of technical replicate assay pairs for which the marker score is consistent. You can examine the distribution of reproducibility with the function gl.report.reproducibility.

Note that the null expectation is not well defined, and the power reduced, if the population from which the putative parent-offspring pairs are drawn contains many sibs. Note also that if an individual has been genotyped twice in the dataset, the replicate pair will be assessed by this script as being in a parent-offspring relationship.

The function gl.filter.parent.offspring will filter out those individuals in a parent offspring relationship.

Note that if your dataset does not contain RepAvg or rdepth among the locus metrics, the filters for reproducibility and read depth are no used.

Function’s output
Plots and table are saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in

- [https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/](https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/)
Value
A set of individuals in parent-offspring relationship. NULL if no parent-offspring relationships were found.

Examples

out <- gl.report.parent.offspring(testset.gl[1:10])

---

gl.report.rdepth  Reports summary of Read Depth for each locus

Description
SNP datasets generated by DArT report AvgCountRef and AvgCountSnp as counts of sequence tags for the reference and alternate alleles respectively. These can be used to back calculate Read Depth. Fragment presence/absence datasets as provided by DArT (SilicoDArT) provide Average Read Depth and Standard Deviation of Read Depth as standard columns in their report. This function reports the read depth by locus for each of several quantiles.

Usage

gl.report.rdepth(
  x,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)

Arguments

x  Name of the genlight object containing the SNP or presence/absence (SilicoDArT) data [required].
plot.out  Specify if plot is to be produced [default TRUE].
plot_theme  Theme for the plot. See Details for options [default theme_dartR()].
plot_colors List of two color names for the borders and fill of the plots [default two_colors].

save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].

verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

The function displays a table of minimum, maximum, mean and quantiles for read depth against possible thresholds that might subsequently be specified in `gl.filter.rdepth`. If plot.out=TRUE, display also includes a boxplot and a histogram to guide in the selection of a threshold for filtering on read depth.

If save2tmp=TRUE, ggplots and relevant tabulations are saved to the session’s temp directory (tempdir).

For examples of themes, see

- https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value

An unaltered genlight object

Author(s)

# SNP data
df <- gl.report.rdepth(testset.gl)
df <- gl.report.rdepth(testset.gs)
```
gl.report.reproducibility

Reports summary of RepAvg (repeatability averaged over both alleles for each locus) or reproducibility (repeatability of the scores for fragment presence/absence)

Description

SNP datasets generated by DArT have an index, RepAvg, generated by reproducing the data independently for 30 of alleles that give a repeatable result, averaged over both alleles for each locus.

In the case of fragment presence/absence data (SilicoDArT), repeatability is the percentage of scores that are repeated in the technical replicate dataset.

Usage

gl.report.reproducibility(
  x,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)

Arguments

- **x**: Name of the genlight object containing the SNP or presence/absence (SilicoDArT) data [required].
- **plot.out**: If TRUE, displays a plot to guide the decision on a filter threshold [default TRUE].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: List of two color names for the borders and fill of the plots [default two_colors].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

The function displays a table of minimum, maximum, mean and quantiles for repeatability against possible thresholds that might subsequently be specified in `gl.filter.reproducibility`.

If `plot.out=TRUE`, display also includes a boxplot and a histogram to guide in the selection of a threshold for filtering on repeatability.

If `save2tmp=TRUE`, ggplots and relevant tabulations are saved to the session’s temp directory (tempdir)

**gl.report.secondaries**  Reports loci containing secondary SNPs in sequence tags and calculates number of invariant sites

**Description**

SNP datasets generated by DArT include fragments with more than one SNP (that is, with secondaries). They are recorded separately with the same CloneID (=AlleleID). These multiple SNP loci within a fragment are likely to be linked, and so you may wish to remove secondaries.

This function reports statistics associated with secondaries, and the consequences of filtering them out, and provides three plots. The first is a boxplot, the second is a barplot of the frequency of secondaries per sequence tag, and the third is the Poisson expectation for those frequencies including an estimate of the zero class (no. of sequence tags with no SNP scored).

**Usage**

```r
gl.report.secondaries(
  x,
  nsim = 1000,
  taglength = 69,
  plot.out = TRUE,
)```
\begin{verbatim}
plot_theme = theme_dartR(),
plot_colors = two_colors,
save2tmp = FALSE,
verbose = NULL
)

Arguments

\textbf{x} \hspace{1cm} Name of the genlight object containing the SNP data [required].
\textbf{nsim} \hspace{1cm} The number of simulations to estimate the mean of the Poisson distribution [default 1000].
\textbf{taglength} \hspace{1cm} Typical length of the sequence tags [default 69].
\textbf{plot.out} \hspace{1cm} Specify if plot is to be produced [default TRUE].
\textbf{plot_theme} \hspace{1cm} Theme for the plot. See Details for options [default theme_dartR()].
\textbf{plot_colors} \hspace{1cm} List of two color names for the borders and fill of the plots [default two_colors].
\textbf{save2tmp} \hspace{1cm} If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
\textbf{verbose} \hspace{1cm} Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set verbosity].

Details

The function \texttt{gl.filter.secondaries} will filter out the loci with secondaries retaining only one sequence tag.

Heterozygosity as estimated by the function \texttt{gl.report.heterozygosity} is in a sense relative, because it is calculated against a background of only those loci that are polymorphic somewhere in the dataset. To allow intercompatibility across studies and species, any measure of heterozygosity needs to accommodate loci that are invariant (autosomal heterozygosity. See Schmidt et al 2021). However, the number of invariant loci are unknown given the SNPs are detected as single point mutational variants and invariant sequences are discarded, and because of the particular additional filtering pre-analysis. Modelling the counts of SNPs per sequence tag as a Poisson distribution in this script allows estimate of the zero class, that is, the number of invariant loci. This is reported, and the veracity of the estimate can be assessed by the correspondence of the observed frequencies against those under Poisson expectation in the associated graphs. The number of invariant loci can then be optionally provided to the function \texttt{gl.report.heterozygosity} via the parameter \texttt{n.invariants}.

In case the calculations for the Poisson expectation of the number of invariant sequence tags fail to converge, try to rerun the analysis with a larger \texttt{nsim} values.

This function now also calculates the number of invariant sites (i.e. nucleotides) of the sequence tags (if TrimmedSequence is present in \texttt{x$other$loc.metrics}) or estimate these by assuming that the average length of the sequence tags is 69 nucleotides. Based on the Poisson expectation of the number of invariant sequence tags, it also estimates the number of invariant sites for these to eventually provide an estimate of the total number of invariant sites.

\textbf{Note}, previous version of \texttt{dartR} would only return an estimate of the number of invariant sequence tags (not sites).
Plots are saved to the session temporary directory (tempdir).

Examples of other themes that can be used can be consulted in:

- [https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/](https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/)

**Value**

A data.frame with the list of parameter values

- n.total.tags Number of sequence tags in total
- n.SNPs.secondaries Number of secondary SNP loci that would be removed on filtering
- n.invariant.tags Estimated number of invariant sequence tags
- n.tags.secondaries Number of sequence tags with secondaries
- n.inv.gen Number of invariant sites in sequenced tags
- mean.len.tag Mean length of sequence tags
- n.invariant Total Number of invariant sites (including invariant sequence tags)
- k Lambda: mean of the Poisson distribution of number of SNPs in the sequence tags

```r
n.inv <- gl.report.secondaries(platypus.gl)
gl.report.heterozygosity(platypus.gl, n.invariant = n.inv[7, 2])
```
gl.report.sexlinked

Identifies loci that are sex linked

Description
Alleles unique to the Y or W chromosome and monomorphic on the X chromosomes will appear in the SNP dataset as genotypes that are heterozygotic in all individuals of the heterogametic sex and homozygous in all individuals of the homogametic sex. This function identifies loci with alleles that behave in this way, as putative sex specific SNP markers.

Usage
```r
gl.report.sexlinked(
  x,
  sex = NULL,
  t.het = 0.1,
  t.hom = 0.1,
  t.pres = 0.1,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = three_colors,
  verbose = NULL
)
```

Arguments
- **x**: Name of the genlight object containing the SNP or presence/absence (SilicoDArT) data [required].
- **sex**: Factor that defines the sex of individuals. See explanation in details [default NULL].
- **t.het**: Tolerance in the heterogametic sex, that is t.het=0.05 means that 5% of the heterogametic sex can be homozygous and still be regarded as consistent with a sex specific marker [default 0.1].
- **t.hom**: Tolerance in the homogametic sex, that is t.hom=0.05 means that 5% of the homogametic sex can be heterozygous and still be regarded as consistent with a sex specific marker [default 0.1].
- **t.pres**: Tolerance in presence, that is t.pres=0.05 means that a silicodart marker can be present in either of the sexes and still be regarded as a sex-linked marker [default 0.1].
- **plot.out**: Creates a plot that shows the heterozygosity of males and females at each loci and shaded area in which loci can be regarded as consistent with a sex specific marker [default TRUE].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: List of three color names for the not sex-linked loci, for the sex-linked loci and for the area in which sex-linked loci appear [default three_colors].
**gl.report.taglength**

Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

**Details**

Sex of the individuals for which sex is known with certainty can be provided via a factor (equal to the length of the number of individuals) or to be held in the variable `x@other$ind.metrics$sex`. Coding is: M for male, F for female, U or NA for unknown/missing. The script abbreviates the entries here to the first character. So, coding of 'Female' and 'Male' works as well. Character are also converted to upper cases.

**Function's output**

This function creates a plot that shows the heterozygosity of males and females at each loci or SNP data or percentage of present/absent in the case of SilicoDArT data.

Examples of other themes that can be used can be consulted in

- [https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/](https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/)

**Value**

Two lists of sex-linked loci, one for XX/XY and one for ZZ/ZW systems and a plot.

**Author(s)**

Arthur Georges, Bernd Gruber & Floriaan Devloo-Delva (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

Other reporting functions: `gl.diagnostics.hwe()`, `gl.report.bases()`, `gl.report.diversity()`, `gl.report.heterozygosity()`, `gl.report.parent.offspring()`, `gl.report.pa()`

**Examples**

```r
out <- gl.report.sexlinked(testset.gl)
out <- gl.report.sexlinked(testset.gs)
```

**Description**

SNP datasets generated by DArT typically have sequence tag lengths ranging from 20 to 69 base pairs. This function reports summary statistics of the tag lengths.
Usage

```r
gl.report.taglength(
  x,
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  plot_colors = two_colors,
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- **x**: Name of the genlight object containing the SNP [required].
- **plot.out**: If TRUE, displays a plot to guide the decision on a filter threshold [default TRUE].
- **plot_theme**: Theme for the plot. See Details for options [default theme_dartR()].
- **plot_colors**: List of two color names for the borders and fill of the plots [default two_colors].
- **save2tmp**: If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity]

Details

The function `gl.filter.taglength` will filter out the loci with a tag length below a specified threshold.

Quantiles are partitions of a finite set of values into q subsets of (nearly) equal sizes. In this function q = 20. Quantiles are useful measures because they are less susceptible to long-tailed distributions and outliers.

Function’s output

The minimum, maximum, mean and a tabulation of tag length quantiles against thresholds are provided. Output also includes a boxplot and a histogram to guide in the selection of a threshold for filtering on tag length.

Plots and table are saved to the temporal directory (tempdir) and can be accessed with the function `gl.print.reports` and listed with the function `gl.list.reports`. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in

- [https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/](https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/)

Value

Returns unaltered genlight object
gl.run.structure

Runs a STRUCTURE analysis using a genlight object

Description

This function takes a genlight object and runs a STRUCTURE analysis based on functions from strataG.

Usage

```r
gl.run.structure(
  x, ...
  exec = ".",
  plot.out = TRUE,
  plot_theme = theme_dartR(),
  save2tmp = FALSE,
  verbose = NULL
)
```

Arguments

- `x` Name of the genlight object containing the SNP data [required].
- `...` Parameters to specify the STRUCTURE run (check `structureRun` within strataG for more details). Parameters are passed to the `structureRun` function. For example you need to set the `k.range` and the type of model you would like to run (nadmix, locprior) etc. If those parameter names do not tell you anything, please make sure you familiarize with the STRUCTURE program (Pritchard 2000).
- `exec` Full path and name+extension where the structure executable is located. E.g. ‘c:/structure/structure.exe’ under Windows. For Mac and Linux it might be something like ‘./structure/structure’ if the executable is in a subfolder ‘structure’ in your home directory [default working directory "."].
plot.out Create an Evanno plot once finished. Be aware k.range needs to be at least three different k steps [default TRUE].
plot_theme Theme for the plot. See details for options [default theme_dartR()].
save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose Set verbosity for this function (though structure output cannot be switched off currently) [default NULL]

Details
The function is basically a convenient wrapper around the beautiful strataG function structureRun (Archer et al. 2016). For a detailed description please refer to this package (see references below). To make use of this function you need to download STRUCTURE for you system (non GUI version) from here STRUCTURE.

Value
An sr object (structure.result list output). Each list entry is a single structurerun output (there are k.range * num.k.rep number of runs). For example the summary output of the first run can be accessed via sr[[1]]$summary or the q-matrix of the third run via sr[[3]]$q.mat. To conveniently summarise the outputs across runs (clumpp) you need to run gl.plot.structure on the returned sr object. For Evanno plots run gl.evanno on your sr object.

Author(s)
Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

References

Examples
```r
# Not run:
#CLUMPP needs to be installed to be able to run the example
#bc <- bandicoot.gl[,1:100]
#sr <- gl.run.structure(bc, k.range = 2:5, num.k.rep = 3, exec = './structure.exe')
#ev <- gl.evanno(sr)
#ev
#qmat <- gl.plot.structure(sr, k=3, CLUMPP='d:/structure/')
#head(qmat)
#gl.map.structure(qmat, bc, scalex=1, scaley=0.5)

## End(Not run)
```
gl.save

Saves an object in compressed binary format for later rapid retrieval

Description

This is a wrapper for saveRDS().

The script saves the object in binary form to the current workspace and returns the input gl object.

Usage

gl.save(x, file, verbose = NULL)

Arguments

x
Name of the genlight object containing SNP genotypes [required].

file
Name of the file to receive the binary version of the object [required].

verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

The input object

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

gl.load

Examples

gl.save(testset.gl,file.path(tempdir(),'testset.rds'))
gl.select.colors  Selects colors from one of several palettes and output as a vector

Description

This script draws upon a number of specified color libraries to extract a vector of colors for plotting, where the script that follows has a color parameter expecting a vector of colors.

Usage

```r
gl.select.colors(
  x = NULL,
  library = NULL,
  palette = NULL,
  ncolors = NULL,
  select = NULL,
  verbose = NULL
)
```

Arguments

- `x`: Optionally, provide a gl object from which to determine the number of populations [default NULL].
- `library`: Name of the color library to be used [default scales::hue_pl].
- `palette`: Name of the color palette to be pulled from the specified library [default is library specific].
- `ncolors`: Number of colors to be displayed and returned [default 9].
- `select`: Select the colors to retain in the output vector [default NULL].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

The available color libraries and their palettes include:

- Library 'brewer' and the palettes available can be listed by RColorBrewer::display.brewer.all() and RColorBrewer::brewer.pal.info.
- Library 'gr.palette' and the palettes available can be listed by grDevices::palette.pals()
- Library 'r.hcl' and the palettes available can be listed by grDevices::hcl.pals()
- Library 'baseR' and the palettes available are: 'rainbow', 'heat', 'topo.colors', 'terrain.colors', 'cm.colors'.

If the nominated palette is not specified, all the palettes will be listed and a default palette will then be chosen.
gl.select.shapes

Selects shapes from the base R shape palette and outputs as a vector

**Description**

This script draws upon the standard R shape palette to extract a vector of shapes for plotting, where the script that follows has a shape parameter expecting a vector of shapes.

**Usage**

```r
gl.select.shapes(x = NULL, select = NULL, verbose = NULL)
```
**gl.select.shapes**

**Arguments**

- **x**: Optionally, provide a gl object from which to determine the number of populations [default NULL].
- **select**: Select the shapes to retain in the output vector [default NULL, all shapes shown and returned].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Details**

By default the shape palette will be displayed in full in the graphics window from which shapes can be selected in a subsequent run, and the vector of shapes returned for later use.

The select parameter can be used to select shapes from the specified 26 shapes available (0-25). For example, select=c(1,1,3) will select shape 1, 1 again and 3 to retain in the final vector. This can be useful for fine-tuning shape selection, and matching colors and shapes.

**Value**

A vector with the required number of shapes

**Author(s)**

Custodian: Arthur Georges – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**See Also**

- `gl.select.colors`

**Examples**

```r
# SET UP DATASET
gl <- testset.gl
levels(pop(gl))<-c(rep('Coast',5),rep('Cooper',3),rep('Coast',5),
rep('MDB',8),rep('Coast',7),rep('Em.subglobosa','Em.victoriae')
# EXAMPLES
shapes <- gl.select.shapes()  # Select and display available shapes
shapes <- gl.select.shapes(select=c(1,1,1,5,8))  # Select set of shapes and check with no. of pops.
```
**gl.set.verbosity**  *Sets the default verbosity level*

**Description**

dartR functions have a verbosity parameter that sets the level of reporting during the execution of the function. The verbosity level, set by parameter `verbose` can be one of: verbose 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report. The default value for verbosity is stored in the `r` environment. This script sets the default value.

**Usage**

```r
gl.set.verbosity(value = 2)
```

**Arguments**

- **value**

  Set the default verbosity to be this value: 0, silent only fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2]

**Value**

- verbosity value [set for all functions]

**Author(s)**

Custodian: Arthur Georges (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

**Examples**

```r
gl <- gl.set.verbosity(value=2)
```

---

**gl.sim.create_dispersal**  *Creates a dispersal file as input for the function gl.sim.WF.run*

**Description**

This function writes a csv file called "dispersal_table.csv" which contains the dispersal variables for each pair of populations to be used as input for the function `gl.sim.WF.run`

The values of the variables can be modified using the columns "transfer_each_gen" and "number_transfers" of this file.

See documentation and tutorial for a complete description of the simulations. These documents can be accessed by typing in the R console: `browseVignettes(package="dartR")"
Usage

```r
gl.sim.create_dispersal(
  number_pops,
  dispersal_type = "all_connected",
  number_transfers = 1,
  transfer_each_gen = 1,
  outpath = tempdir(),
  outfile = "dispersal_table.csv",
  verbose = NULL
)
```

Arguments

- **number_pops**: Number of populations [required].
- **dispersal_type**: One of: "all_connected", "circle" or "line" [default "all_connected"].
- **number_transfers**: Number of dispersing individuals. This value can be modified by hand after the file has been created [default 1].
- **transfer_each_gen**: Interval of number of generations in which dispersal occur. This value can be modified by hand after the file has been created [default 1].
- **outpath**: Path where to save the output file. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory [default tempdir(), mandated by CRAN].
- **outfile**: File name of the output file [default 'dispersal_table.csv'].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

Writes csv file containing the dispersal variables for each pair of populations to be used as input for the function `gl.sim.WF.run`.

Author(s)

Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

See Also

Other simulation functions: `gl.sim.WF.run()`, `gl.sim.WF.table()`

Examples

```r
gl.sim.create_dispersal(number_pops=10)
```
gl.sim.emigration

Simulates emigration between populations

Description

A function that allows to exchange individuals of populations within a genlight object (=simulate emigration between populations).

Usage

gl.sim.emigration(x, perc.mig = NULL, emi.m = NULL, emi.table = NULL)

Arguments

x
A genlight or list of genlight objects [required].

perc.mig
Percentage of individuals that migrate (emigrates = nInd times perc.mig) [default NULL].

emi.m
Probabilistic emigration matrix (emigrate from=column to=row) [default NULL]

emi.table
If presented emi.m matrix is ignored. Deterministic emigration as specified in the matrix (a square matrix of dimension of the number of populations). e.g. an entry in the `emi.table[2,1]<- 5` means that five individuals emigrate from population 1 to population 2 (from=columns and to=row) [default NULL].

Details

There are two ways to specify emigration. If an emi.table is provided (a square matrix of dimension of the populations that specifies the emigration from column x to row y), then emigration is deterministic in terms of numbers of individuals as specified in the table. If perc.mig and emi.m are provided, then emigration is probabilistic. The number of emigrants is determined by the population size times the perc.mig and then the population where to migrate to is taken from the relative probability in the columns of the emi.m table.

Be aware if the diagonal is non zero then migration can occur into the same patch. So most often you want to set the diagonal of the emi.m matrix to zero. Which individuals is moved is random, but the order is in the order of populations. It is possible that an individual moves twice within an emigration call(as there is no check, so an individual moved from population 1 to 2 can move again from population 2 to 3).

Value

A list or a single [depends on the input] genlight object, where emigration between population has happened

Author(s)

Custodian: Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)
Examples

```r
x <- possums.gl
#one individual moves from every population to
every other population
emi.tab <- matrix(1, nrow=nPop(x), ncol=nPop(x))
diag(emi.tab)<- 0
np <- gl.sim.emigration(x, emi.table=emi.tab)
np
```

Description

This function simulates individuals based on the allele frequencies of a genlight object. The output is a genlight object with the same number of loci as the input genlight object.

Usage

```r
gl.sim.ind(x, n = 50, popname = NULL)
```

Arguments

- **x**: Name of the genlight object containing the SNP data [required].
- **n**: Number of individuals that should be simulated [default 50].
- **popname**: A population name for the simulated individuals [default NULL].

Details

The function can be used to simulate populations for sampling designs or for power analysis. Check the example below where the effect of drift is explored, by simply simulating several generation a genlight object and putting in the allele frequencies of the previous generation. The beauty of the function is, that it is lightning fast. Be aware this is a simulation and to avoid lengthy error checking the function crashes if there are loci that have just NAs. If such a case can occur during your simulation, those loci need to be removed, before the function is called.

Value

A genlight object with n individuals.

Author(s)

Bernd Gruber (bernd.gruber@canberra.edu.au)
Examples

```r
# Simulate drift over 10 generation
# assuming a bottleneck of only 10 individuals
# [ignoring effect of mating and mutation]
# Simulate 20 individuals with no structure and 50 SNP loci
founder <- glSim(n.ind = 20, n.snp.nonstruc = 50, ploidy=2)
#number of fixed loci in the first generation
res <- sum(colMeans(as.matrix(founder), na.rm=TRUE) %%2 ==0)
simgl <- founder
#49 generations of only 10 individuals
for (i in 2:50)
{
  simgl <- gl.sim.ind(simgl, n=10, popname='sims')
  res[i]<- sum(colMeans(as.matrix(simgl), na.rm=TRUE) %%2 ==0)
}
plot(1:50, res, type='b', xlab='generation', ylab='# fixed loci')
```

---

**gl.sim.mutate**

*Simulates mutations within a genlight object*

**Description**

This script is intended to be used within the simulation framework of dartR. It adds the ability to add a constant mutation rate across all loci. Only works currently for biallelic data sets (SNPs). Mutation rate is checking for all alleles position and mutations at loci with missing values are ignored and in principle 'double mutations' at the same loci can occur, but should be rare.

**Usage**

```r
gl.sim.mutate(x, mut.rate = 1e-06)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data [required].
- `mut.rate` Constant mutation rate over nInd*nLoc*2 possible locations [default 1e-6]

**Value**

Returns a genlight object with the applied mutations

**Author(s)**

Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)
`gl.sim.offspring`  

**Examples**

```r
b2 <- gl.sim.mutate(bandicoot.gl, mut.rate=1e-4 )
#check the mutations that have occurred
table(as.matrix(bandicoot.gl), as.matrix(b2))
```

---

**gl.sim.offspring**  

`Simulates a specified number of offspring based on alleles provided by potential father(s) and mother(s)`

**Description**

This takes a population (or a single individual) of fathers (provided as a genlight object) and mother(s) and simulates offspring based on 'random' mating. It can be used to simulate population dynamics and check the effect of those dynamics and allele frequencies, number of alleles. Another application is to simulate relatedness of siblings and compare it to actual relatedness found in the population to determine kinship.

**Usage**

```r
gl.sim.offspring(fathers, mothers, noffpermother, sexratio = 0.5)
```

**Arguments**

- `fathers`: Genlight object of potential fathers [required].
- `mothers`: Genlight object of potential mothers simulated [required].
- `noffpermother`: Number of offspring per mother [required].
- `sexratio`: The sex ratio of simulated offspring (females / females + males, 1 equals 100 percent females) [default 0.5].

**Value**

A genlight object with n individuals.

**Author(s)**

Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

**Examples**

```r
#Simulate 10 potential fathers
gl.fathers <- glSim(10, 20, ploidy=2)
#Simulate 10 potential mothers
gl.mothers <- glSim(10, 20, ploidy=2)
gl.sim.offspring(gl.fathers, gl.mothers, 2, sexratio=0.5)
```
gl.sim.WF.run  Runs Wright-Fisher simulations

Description
This function simulates populations made up of diploid organisms that reproduce in non-overlapping generations. Each individual has a pair of homologous chromosomes that contains interspersed selected and neutral loci. For the initial generation, the genotype for each individual’s chromosomes is randomly drawn from distributions at linkage equilibrium and in Hardy-Weinberg equilibrium.

See documentation and tutorial for a complete description of the simulations. These documents can be accessed at http://georges.biomatix.org/dartR

Usage

gl.sim.WF.run(
  file_var,
  ref_table,
  x = NULL,
  file_dispersal = NULL,
  number_iterations = 1,
  every_gen = 10,
  sample_percent = 50,
  store_phase1 = FALSE,
  interactive_vars = TRUE,
  seed = NULL,
  verbose = NULL,
  ...
)

Arguments

<table>
<thead>
<tr>
<th>Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_var</td>
<td>Path of the variables file 'sim_variables.csv' (see details) [required if interactive_vars = FALSE].</td>
</tr>
<tr>
<td>ref_table</td>
<td>Reference table created by the function gl.sim.WF.table [required].</td>
</tr>
<tr>
<td>x</td>
<td>Name of the genlight object containing the SNP data to extract values for some simulation variables (see details) [default NULL].</td>
</tr>
<tr>
<td>file_dispersal</td>
<td>Path of the file with the dispersal table created with the function gl.sim.create_dispersal [default NULL].</td>
</tr>
<tr>
<td>number_iterations</td>
<td>Number of iterations of the simulations [default 1].</td>
</tr>
<tr>
<td>every_gen</td>
<td>Generation interval at which simulations should be stored in a genlight object [default 10].</td>
</tr>
<tr>
<td>sample_percent</td>
<td>Percentage of individuals, from the total population, to sample and save in the genlight object every generation [default 50].</td>
</tr>
<tr>
<td>store_phase1</td>
<td>Whether to store simulations of phase 1 in genlight objects [default FALSE].</td>
</tr>
</tbody>
</table>
interactive_vars
Run a shiny app to input interactively the values of simulations variables [default TRUE].

seed
Set the seed for the simulations [default NULL].

verbose
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress
and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Any variable and its value can be added separately within the function, will be
changed over the input value supplied by the csv file. See tutorial.

Details
Values for simulation variables can be submitted into the function interactively through a shiny app
if interactive_vars = TRUE. Optionally, if interactive_vars = FALSE, values for variables can be
submitted by using the csv file 'sim_variables.csv' which can be found by typing in the R console:
system.file('extdata', 'sim_variables.csv', package = 'dartR').
The values of the variables can be modified using the third column (“value”) of this file.
The output of the simulations can be analysed seemingly with other dartR functions.
If a genlight object is used as input for some of the simulation variables, this function access the
information stored in the slots x$position and x$chromosome.
To show further information of the variables in interactive mode, it might be necessary to call first:
'library(shinyBS)' for the information to be displayed.
The main characteristics of the simulations are:
• Simulations can be parameterised with real-life genetic characteristics such as the number, lo-
cation, allele frequency and the distribution of fitness effects (selection coefficients and domi-
nance) of loci under selection.
• Simulations can recreate specific life histories and demographics, such as source populations,
dispersal rate, number of generations, founder individuals, effective population size and cen-
sus population size.
• Each allele in each individual is an agent (i.e., each allele is explicitly simulated).
• Each locus can be customisable regarding its allele frequencies, selection coefficients, and
dominance.
• The number of loci, individuals, and populations to be simulated is only limited by computing
resources.
• Recombination is accurately modeled, and it is possible to use real recombination maps as
input.
• The ratio between effective population size and census population size can be easily con-
trolled.
• The output of the simulations are genlight objects for each generation or a subset of genera-
tions.
• Genlight objects can be used as input for some simulation variables.

Value
Returns genlight objects with simulated data.
**gl.sim.WF.table**

**Author(s)**

Custodian: Luis Mijangos – Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr)

**See Also**

`gl.sim.WF.table`

Other simulation functions: `gl.sim.WF.table()`, `gl.sim.create_dispersal()`

**Examples**

```r
## Not run:
ref_table <- gl.sim.WF.table(file_var=system.file('extdata',
  'ref_variables.csv', package = 'dartR'),interactive_vars = FALSE)
res_sim <- gl.sim.WF.run(file_var = system.file('extdata',
  'sim_variables.csv', package = 'dartR'),ref_table=ref_table,
  interactive_vars = FALSE)
## End(Not run)
```

---

**gl.sim.WF.table**

*Creates the reference table for running gl.sim.WF.run*

**Description**

This function creates a reference table to be used as input for the function `gl.sim.WF.run`. The created table has seven columns with the following information for each locus to be simulated:

- **q** - initial frequency.
- **h** - dominance coefficient.
- **s** - selection coefficient.
- **c** - recombination rate.
- **loc_bp** - chromosome location in base pairs.
- **loc_cM** - chromosome location in centiMorgans.
- **chr_name** - chromosome name.
- **type** - SNP type.

The reference table can be further modified as required.

See documentation and tutorial for a complete description of the simulations. These documents can be accessed at [http://georges.biomatix.org/dartR](http://georges.biomatix.org/dartR)
Usage

```r
gl.sim.WF.table(
  file_var,
  x = NULL,
  file_targets_sel = NULL,
  file_r_map = NULL,
  interactive_vars = TRUE,
  seed = NULL,
  verbose = NULL,
  ...
)
```

Arguments

- **file_var**: Path of the variables file 'ref_variables.csv' (see details) [required if interactive_vars = FALSE].
- **x**: Name of the genlight object containing the SNP data to extract values for some simulation variables (see details) [default NULL].
- **file_targets_sel**: Path of the file with the targets for selection (see details) [default NULL].
- **file_r_map**: Path of the file with the recombination map (see details) [default NULL].
- **interactive_vars**: Run a shiny app to input interactively the values of simulation variables [default TRUE].
- **seed**: Set the seed for the simulations [default NULL].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].
- **...**: Any variable and its value can be added separately within the function, will be changed over the input value supplied by the csv file. See tutorial.

Details

Values for the variables to create the reference table can be submitted into the function interactively through a Shiny app if interactive_vars = TRUE. Optionally, if interactive_vars = FALSE, values for variables can be submitted by using the csv file 'ref_variables.csv' which can be found by typing in the R console: `system.file('extdata', 'ref_variables.csv', package = 'dartR')`

The values of the variables can be modified using the third column ("value") of this file.

If a genlight object is used as input for some of the simulation variables, this function access the information stored in the slots `x$position` and `x$chromosome`.

Examples of the format required for the recombination map file and the targets for selection file can be found by typing in the R console:
- `system.file('extdata', 'fly_recom_map.csv', package = 'dartR')`
- `system.file('extdata', 'fly_targets_of_selection.csv', package = 'dartR')`

To show further information of the variables in interactive mode, it might be necessary to call first: `library(shinyBS)` for the information to be displayed.
Value
Returns a list with the reference table used as input for the function `gl.sim.WF.run` and a table with the values variables used to create the reference table.

Author(s)
Custodian: Luis Mijangos – Post to https://groups.google.com/d/forum/dartr

See Also
`gl.sim.WF.run`  
Other simulation functions: `gl.sim.WF.run()`, `gl.sim.create_dispersal()`

Examples
```r
ref_table <- gl.sim.WF.table(file_var=system.file('extdata', 'ref_variables.csv', package = 'dartR'),interactive_vars = FALSE)
# Not run:
# uncomment to run
res_sim <- gl.sim.WF.run(file_var = system.file('extdata', 'sim_variables.csv', package = 'dartR'),ref_table=ref_table, interactive_vars = FALSE)
```

`gl.smearplot`  
Smear plot of SNP or presence/absence (SilicoDArT) data

Description
Each locus is color coded for scores of 0, 1, 2 and NA for SNP data and 0, 1 and NA for presence/absence (SilicoDArT) data. Individual labels can be added and individuals can be grouped by population.

Plot may become cluttered if ind_labels If there are too many individuals, it is best to use ind_labels_size = 0.

Usage
```r
gl.smearplot(
  x,
  ind_labels = FALSE,
  group_pop = FALSE,
  ind_labels_size = 10,
  plot_colors = colorRampPalette(c("royalblue3", "firebrick1"))(3),
  posi = "bottom",
  save2tmp = FALSE,
  verbose = NULL
)
```
gl.subsample.loci

Subsamples n loci from a genlight object and return it as a genlight object

Description

This is a support script, to subsample a genlight {adegenet} object based on loci. Two methods are used to subsample, random and based on information content.

Usage

```r
gl.subsample.loci(x, n, method = "random", mono.rm = FALSE, verbose = NULL)
```
gl.test.heterozygosity

Tests the difference in heterozygosity between populations taken pair-wise

Description

Calculates the expected heterozygosities for each population in a genlight object, and uses re-randomization to test the statistical significance of differences in heterozygosity between populations taken pairwise.

Usage

```r
gl.test.heterozygosity(
  x,
  nreps = 100,
  alpha1 = 0.05,
  alpha2 = 0.01,
  plot.out = TRUE,
```
max_plots = 6,
plot_theme = theme_dartR(),
plot_colors = two_colors,
save2tmp = FALSE,
verbose = NULL
)

Arguments

x A genlight object containing the SNP genotypes [required].
nreps Number of replications of the re-randomization [default 1,000].
alpha1 First significance level for comparison with diff=0 on plot [default 0.05].
alpha2 Second significance level for comparison with diff=0 on plot [default 0.01].
plot.out If TRUE, plots a sampling distribution of the differences for each comparison [default TRUE].
max_plots Maximum number of plots to print per page [default 6].
plot_theme Theme for the plot. See Details for options [default theme_dartR()].
plot_colors List of two color names for the borders and fill of the plots [default two_colors].
save2tmp If TRUE, saves any ggplots and listings to the session temporary directory (tempdir) [default FALSE].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

Function’s output

If plot.out = TRUE, plots are created showing the sampling distribution for the difference between each pair of heterozygosities, marked with the critical limits alpha1 and alpha2, the observed heterozygosity, and the zero value (if in range).

Plots and table are saved to the temporal directory (tempdir) and can be accessed with the function gl.print.reports and listed with the function gl.list.reports. Note that they can be accessed only in the current R session because tempdir is cleared each time that the R session is closed.

Examples of other themes that can be used can be consulted in

• https://ggplot2.tidyverse.org/reference/ggtheme.html and
• https://yutannihilation.github.io/allYourFigureAreBelongToUs/ggthemes/

Value

A dataframe containing population labels, heterozygosities and sample sizes

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)
Examples

```
out <- gl.test.heterozygosity(bandicoot.gl, nreps=10, verbose=3, plot.out=TRUE)
```

### gl.tree.nj

*Outputs an nj tree to summarize genetic similarity among populations*

#### Description

This function is a wrapper for the `nj{ape}` function applied to Euclidian distances calculated from the genlight object.

#### Usage

```r
gl.tree.nj(
  x,
  type = "phylogram",
  outgroup = NULL,
  labelsize = 0.7,
  treefile = NULL,
  verbose = NULL
)
```

#### Arguments

- `x` : Name of the genlight object containing the SNP data [required].
- `type` : Type of dendrogram "phylogram" | "cladogram" | "fan" | "unrooted" [default "phylogram"].
- `outgroup` : Vector containing the population names that are the outgroups [default NULL].
- `labelsize` : Size of the labels as a proportion of the graphics default [default 0.7].
- `treefile` : Name of the file for the tree topology using Newick format [default NULL].
- `verbose` : Specify the level of verbosity: 0, silent, fatal errors only; 1, flag function begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

#### Value

A tree file of class phylo.

#### Author(s)

Custodian: Arthur Georges (Post to https://groups.google.com/d/forum/dartr)

#### Examples

```
# SNP data
gl.tree.nj(testset.gl,type='fan')
# Tag P/A data
gl.tree.nj(testset.gs,type='fan')
```
gl.write.csv  

*Writes out data from a genlight object to csv file*

**Description**

This script writes to file the SNP genotypes with specimens as entities (columns) and loci as attributes (rows). Each row has associated locus metadata. Each column, with header of specimen id, has population in the first row.

The data coding differs from the DArT 1row format in that 0 = reference homozygous, 2 = alternate homozygous, 1 = heterozygous, and NA = missing SNP assignment.

**Usage**

```r
gl.write.csv(x, outfile = "outfile.csv", outpath = tempdir(), verbose = NULL)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data [required].
- `outfile` File name of the output file (including extension) [default "outfile.csv"].
- `outpath` Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Value**

Saves a genlight object to csv, returns NULL.

**Author(s)**

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

**Examples**

```r
# SNP data
gl.write.csv(testset.gl, outfile='SNP_1row.csv')
# Tag P/A data
gl.write.csv(testset.gs, outfile='PA_1row.csv')
```
### gl2bayescan

**Converts a genlight object into a format suitable for input to Bayescan**

**Description**

The output text file contains the SNP data and relevant Bayescan command lines to guide input.

**Usage**

```r
gl2bayescan(x, outfile = "bayescan.txt", outpath = tempdir(), verbose = NULL)
```

**Arguments**

- **x**: Name of the genlight object containing the SNP data [required].
- **outfile**: File name of the output file (including extension) [default bayescan.txt].
- **outpath**: Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Author(s)**

Custodian: Luis Mijangos (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

**References**

**Examples**

```r
out <- gl2bayescan(testset.gl)
```

### gl2demerelate

**Creates a dataframe suitable for input to package {Demerelate} from a genlight {adegenet} object**

**Description**

Creates a dataframe suitable for input to package {Demerelate} from a genlight {adegenet} object.

**Usage**

```r
gl2demerelate(x, verbose = NULL)
```
Arguments

x  Name of the genlight object containing the SNP data [required].

verbose  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity]

Value

A dataframe suitable as input to package {Demerelate}

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

Examples

df <- gl2demerelate(testset.gl)

Description

The output of this function are three files:

• genotype file: contains genotype data for each individual at each SNP with an extension 'eigenstratgeno.'
• snp file: contains information about each SNP with an extension 'snp.'
• indiv file: contains information about each individual with an extension 'ind.'

Usage

```r
gl2eigenstrat(
  x,
  outfile = "gl_eigenstrat",
  outpath = tempdir(),
  snp_pos = 1,
  snp_chr = 1,
  pos_cM = 0,
  sex_code = "unknown",
  phen_value = "Case",
  verbose = NULL
)
```
Arguments

- `x`: Name of the genlight object containing the SNP data [required].
- `outfile`: File name of the output file [default 'gl_eigenstrat'].
- `outpath`: Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
- `snp_pos`: Field name from the slot loc.metrics where the SNP position is stored [default 1].
- `snp_chr`: Field name from the slot loc.metrics where the chromosome of each is stored [default 1].
- `pos_cm`: A vector, with as many elements as there are loci, containing the SNP position in morgans or centimorgans [default 1].
- `sex_code`: A vector, with as many elements as there are individuals, containing the sex code ('male', 'female', 'unknown') [default 'unknown'].
- `phen_value`: A vector, with as many elements as there are individuals, containing the phenotype value ('Case', 'Control') [default 'Case'].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

Eigenstrat only accepts chromosomes coded as numeric values, as follows: X chromosome is encoded as 23, Y is encoded as 24, mtDNA is encoded as 90, and XY is encoded as 91. SNPs with illegal chromosome values, such as 0, will be removed.

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

References

Examples

```r
gl2eigenstrat(platypus.gl,snp_pos='ChromPos_Platypus_Chrom_NCBIV1',
              snp_chr = 'Chrom_Platypus_Chrom_NCBIV1')
```
**gl2fasta**  
*Concatenates DArT trimmed sequences and outputs a FASTA file*

**Description**
Concatenated sequence tags are useful for phylogenetic methods where information on base frequencies and transition and transversion ratios are required (for example, Maximum Likelihood methods). Where relevant, heterozygous loci are resolved before concatenation by either assigning ambiguity codes or by random allele assignment.

**Usage**

```r
gl2fasta(
  x,
  method = 1,
  outfile = "output.fasta",
  outpath = tempdir(),
  probar = FALSE,
  verbose = NULL
)
```

**Arguments**

- **x**
  Name of the genlight object containing the SNP data [required].
- **method**
  One of 1 | 2 | 3 | 4. Type method=0 for a list of options [method=1].
- **outfile**
  Name of the output file (fasta format) ["output.fasta"].
- **outpath**
  Path where to save the output file (set to tempdir by default)
- **probar**
  If TRUE, a progress bar will be displayed for long loops [default = TRUE].
- **verbose**
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

**Details**

Four methods are employed:

Method 1 – heterozygous positions are replaced by the standard ambiguity codes. The resultant sequence fragments are concatenated across loci to generate a single combined sequence to be used in subsequent ML phylogenetic analyses.

Method 2 – the heterozygous state is resolved by randomly assigning one or the other SNP variant to the individual. The resultant sequence fragments are concatenated across loci to generate a single composite haplotype to be used in subsequent ML phylogenetic analyses.

Method 3 – heterozygous positions are replaced by the standard ambiguity codes. The resultant SNP bases are concatenated across loci to generate a single combined sequence to be used in subsequent MP phylogenetic analyses.
Method 4 – the heterozygous state is resolved by randomly assigning one or the other SNP variant to the individual. The resultant SNP bases are concatenated across loci to generate a single composite haplotype to be used in subsequent MP phylogenetic analyses.

Trimmed sequences for which the SNP has been trimmed out, rarely, by adapter mis-identity are deleted.

The script writes out the composite haplotypes for each individual as a fastA file. Requires 'Trimmed-Sequence' to be among the locus metrics (@other$loc.metrics) and information of the type of alleles (slot loc.all e.g. 'G/A') and the position of the SNP in slot position of the 'genlight' object (see testset.gl@position and testset.gl@loc.all for how to format these slots.)

Value

A new gl object with all loci rendered homozygous.

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

Examples

```r
gl <- gl.filter.reproducibility(testset.gl,t=1)
gl <- gl.filter.overshoot(gl,verbose=3)
gl <- gl.filter.callrate(testset.gl,t=.98)
gl <- gl.filter.monomorphs(gl)
gl2fasta(gl, method=1, outfile='test.fasta',verbose=3)
```

---

**gl2faststructure**

Converts a genlight object into faststructure format (to run faststructure elsewhere)

Description

Recodes in the quite specific faststructure format (e.g. first six columns need to be there, but are ignored...check faststructure documentation (if you find any :-() )

Usage

```r
gl2faststructure(  
  x,  
  outfile = "gl.str",  
  outpath = tempdir(),  
  probar = FALSE,  
  verbose = NULL  
)
```
Arguments

x                          Name of the genlight object containing the SNP data [required].
outfile                   File name of the output file (including extension) [default "gl.str"].
outpath                   Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.
probar                     Switch to show/hide progress bar [default FALSE].
verbose                   Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

The script writes out the a file in faststructure format.

**gl2gds**

*Converts a genlight object into gds format*

Description

Package SNPRelate relies on a bit-level representation of a SNP dataset that competes with {ade-genet} genlight objects and associated files. This function converts a genlight object to a gds format file.

Usage

gl2gds(
  x,
  outfile = "gl_gds.gds",
  outpath = tempdir(),
  snp_pos = "0",
  snp_chr = "0",
  chr_format = "character",
  verbose = NULL
)

Arguments

x                          Name of the genlight object containing the SNP data [required].
outfile                   File name of the output file (including extension) [default 'gl_gds.gds'].
outpath                   Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.
### gl2genalex

Converts a genlight object into a format suitable for input to genalex

</tr>
</tbody>
</table>

**Details**

This function orders the SNPS by chromosome and by position before converting to SNPRelate format, as required by this package.

The chromosome of each SNP can be a character or numeric, as described in the vignette of SNPRelate: `snp.chromosome, an integer or character mapping for each chromosome. Integer: numeric values 1-26, mapped in order from 1-22, 23=X, 24=XY (the pseudoautosomal region), 25=Y, 26=M (the mitochondrial probes), and 0 for probes with unknown positions; it does not allow NA. Character: “X”, “XY”, “Y” and “M” can be used here, and a blank string indicating unknown position.’

When using some functions from package SNPRelate with datasets other than humans it might be necessary to use the option autosome.only=FALSE to avoid detecting chromosome coding. So, it is important to read the documentation of the function before using it.

The chromosome information for unmapped SNPS is coded as 0, as required by SNPRelate.

Remember to close the GDS file before working in a different GDS object with the function `snpgdsClose` (package SNPRelate).

**Author(s)**

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

**Examples**

```r
gl2gds(platypus.gl, snp_pos="ChromPos_Platypus_Chrom_NCBIv1", snp_chr = 'Chrom_Platypus_Chrom_NCBIv1')
```

---

**Description**

The output csv file contains the snp data and other relevant lines suitable for genalex. This script is a wrapper for `genind2genalex` (package poppr).
Usage

```r
gl2genalex(
  x,
  outfile = "genalex.csv",
  outpath = tempdir(),
  overwrite = FALSE,
  verbose = NULL
)
```

Arguments

- `x`: Name of the genlight object containing the SNP data [required].
- `outfile`: File name of the output file (including extension) [default 'genalex.csv'].
- `outpath`: Path where to save the output file [default tempdir()].
- `overwrite`: If FALSE and filename exists, then the file will not be overwritten. Set this option to TRUE to overwrite the file [default FALSE].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Author(s)

Custodian: Luis Mijangos, Author: Katrin Hohwieler, wrapper Arthur Georges (Post to https://groups.google.com/d/forum/dartr)

References

Examples

```r
gl2genalex(testset.gl, outfile='testset.csv')
```

The `gl2genepop` function converts a genlight object into genepop format (and file). The genepop format is used by several external applications (for example Neestimator2 [http://www.molecularfisherieslaboratory.com.au/neestimator-software/]). So the main idea is to create the genepop file and then run the other software externally. As a feature, the genepop file is also returned as an invisible data.frame by the function.
Usage

gl2genepop(
  x,
  outfile = "genepop.gen",
  outpath = tempdir(),
  pop_order = "alphabetic",
  output_format = "2_digits",
  verbose = NULL
)

Arguments

  x                   Name of the genlight object containing the SNP data [required].
  outfile            File name of the output file [default 'genepop.gen'].
  outpath            Path where to save the output file. Use outpath=getwd() or outpath='.:' when
                     calling this function to direct output files to your working directory [default
                     tempdir(), mandated by CRAN].
  pop_order          Order of the output populations either "alphabetic" or a vector of population
                     names in the order required by the user (see examples) [default "alphabetic"].
  output_format      Whether to use a 2-digit format ("2_digits") or 3-digits format ("3_digits") [de-
                     fault "2_digits"].
  verbose            Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress
                     and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Value

  Invisible data frame in genepop format

Author(s)

  Custodian: Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

Examples

## Not run:
# SNP data
geno <- gl2genepop(testset.gl[1:3,1:9])
head(geno)
test <- gl.filter.callrate(platypus.gl,threshold = 1)
popNames(test)
gl2genepop(test, pop_order = c("TENTERFIELD","SEVERN_ABOVE","SEVERN_BELOW"),
            output_format="3_digits")

## End(Not run)
gl2geno

Converts a genlight object to geno format from package LEA

Description

The function converts a genlight object (SNP or presence/absence i.e. SilicoDArT data) into a file in the 'geno' and the 'lfmm' formats from (package LEA).

Usage

```r
gl2geno(x, outfile = "gl_geno", outpath = tempdir(), verbose = NULL)
```

Arguments

- **x**: Name of the genlight object containing the SNP or presence/absence (SilicoDArT) data [required].
- **outfile**: File name of the output file [default 'gl_geno'].
- **outpath**: Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

Examples

```r
# SNP data
gl2geno(testset.gl)
# Tag P/A data
gl2geno(testset.gs)
```

---

gl2gi

Converts a genlight object to genind object

Description

Converts a genlight object to genind object

Usage

```r
gl2gi(x, probar = FALSE, verbose = NULL)
```
Arguments

- **x**: A genlight object [required].
- **probar**: If TRUE, a progress bar will be displayed for long loops [default TRUE].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

This function uses a faster version of dl2genind (from the adegenet package).

Value

A genind object, with all slots filled.

Author(s)

Bernd Gruber (Post to https://groups.google.com/d/forum/dartr)

---

**gl2hiphop**

Converts a genlight objects into hiphop format

Description

This function exports genlight objects to the format used by the parentage assignment R package hiphop. Hiphop can be used for paternity and maternity assignment and outperforms conventional methods where closely related individuals occur in the pool of possible parents. The method compares the genotypes of offspring with any combination of potentials parents and scores the number of mismatches of these individuals at bi-allelic genetic markers (e.g. Single Nucleotide Polymorphisms).

Usage

```r
gl2hiphop(x, verbose = NULL)
```

Arguments

- **x**: Name of the genlight object containing the SNP data [required].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

Dataframe containing all the genotyped individuals (offspring and potential parents) and their genotypes scored using bi-allelic markers.
gl2phylip

Author(s)
Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

References

Examples
result <- gl2hiphop(testset.gl)

---

gl2phylip

Creates a Phylip input distance matrix from a genlight (SNP) adegenet object

Description
This function calculates and returns a matrix of Euclidean distances between populations and produces an input file for the phylogenetic program Phylip (Joe Felsenstein).

Usage

```r
gl2phylip(
  x,
  outfile = "phyinput.txt",
  outpath = tempdir(),
  bstrap = 1,
  verbose = NULL
)
```

Arguments

- **x**: Name of the genlight object containing the SNP or presence/absence (SilicoDArT) data [required].
- **outfile**: Name of the file to become the input file for phylip [default "phyinput.txt"].
- **outpath**: Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
- **bstrap**: Number of bootstrap replicates [default 1].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity]
gl2plink

Value

Matrix of Euclidean distances between populations.

Author(s)

Custodian: Arthur Georges (Post to https://groups.google.com/d/forum/dartr)

Examples

result <- gl2phylip(testset.gl, outfile='test.txt', bstrap=10)

---

gl2plink

Converts a genlight object into PLINK format

Description

This function exports a genlight object into PLINK format and save it into a file. This function produces the following PLINK files: bed, bim, fam, ped and map.

Usage

gl2plink(
  x, 
  plink_path = getwd(), 
  bed_file = FALSE, 
  outfile = "gl_plink", 
  outpath = tempdir(), 
  chr_format = "character", 
  pos_cM = "0", 
  ID_dad = "0", 
  ID_mom = "0", 
  sex_code = "unknown", 
  phen_value = "0", 
  verbose = NULL
)

Arguments

x Name of the genlight object containing the SNP data [required].
plink_path Path of PLINK binary file [default getwd()].
bed_file Whether create PLINK files .bed, .bim and .fam [default FALSE].
outfile File name of the output file [default 'gl_plink'].
outpath Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.
Whether chromosome information is stored as 'numeric' or as 'character', see details [default 'character'].

A vector, with as many elements as there are loci, containing the SNP position in morgans or centimorgans [default '0'].

A vector, with as many elements as there are individuals, containing the ID of the father, '0' if father isn’t in dataset [default '0'].

A vector, with as many elements as there are individuals, containing the ID of the mother, '0' if mother isn’t in dataset [default '0'].

A vector, with as many elements as there are individuals, containing the sex code ('male', 'female', 'unknown'). Sex information needs just to start with an "F" or "f" for females, with an "M" or "m" for males and with a "U", "u" or being empty if the sex is unknown [default 'unknown'].

A vector, with as many elements as there are individuals, containing the phenotype value. '1' = control, '2' = case, '0' = unknown [default '0'].

Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Details

To create PLINK files .bed, .bim and .fam (bed_file = TRUE), it is necessary to download the binary file of PLINK 1.9 and provide its path (plink_path). The binary file can be downloaded from: https://www.cog-genomics.org/plink/

After downloading, unzip the file, access the unzipped folder and move the binary file ("plink") to your working directory.

If you are using a Mac, you might need to open the binary first to grant access to the binary.

The chromosome of each SNP can be a character or numeric. The chromosome information for unmapped SNPS is coded as 0. Family ID is taken from x$pop. Within-family ID (cannot be '0') is taken from indNames(x). Variant identifier is taken from locNames(x). SNP position is taken from the accessor x$position. Chromosome name is taken from the accessor x$chromosome Note that if names of populations or individuals contain spaces, they are replaced by an underscore "_".

If you like to use chromosome information when converting to plink format and your chromosome names are not from human, you need to change the chromosome names as 'contig1', 'contig2', etc. as described in the section "Nonstandard chromosome IDs" in the following link: https://www.cog-genomics.org/plink/1.9/input

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

References

**gl2related**

*Converts a genlight object to format suitable to be run with Coancestry*

**Description**

The output txt file contains the SNP data and an additional column with the names of the individual. The file then can be used and loaded into coancestry or - if installed - run with the related package. Be aware the related package was crashing in previous versions, but in general is using the same code as coancestry and therefore should have identical results. Also running coancestry with thousands of SNPs via the GUI seems to be not reliable and therefore for comparisons between coancestry and related we suggest to use the command line version of coancestry.

**Usage**

```r
gl2related(
  x, 
  outfile = "related.txt",
  outpath = tempdir(),
  save = TRUE,
  verbose = NULL
)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data [required].
- `outfile` File name of the output file (including extension) [default ’related.txt’].
- `outpath` Path where to save the output file [default tempdir()].
- `save` A switch if you want to save the file or not. This might be useful for someone who wants to use the coancestry function to calculate relatedness and not export to coancestry. See the example below [default TRUE].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.setverbosity].

**Value**

A data.frame that can be used to run with the related package
Author(s)

Bernd Gruber (bugs? Post to https://groups.google.com/d/forum/dartr)

References

Examples

gtd <- gl2related(bandicoot.gl[1:10,1:20], save=FALSE)
## Not run:
##running with the related package
#install.packages('related', repos='http://R-Forge.R-project.org')
library(related)
coan <- coancestry(gtd, wang=1)
head(coan$relatedness)
##check ?coancestry for information how to use the function.
## End(Not run)

Description

This function exports a genlight object into a SNPassoc object. See package SNPassoc for details. This function needs package SNPassoc. At the time of writing (August 2020) the package was no longer available from CRAN. To install the package check their github repository. https://github.com/isglobal-brge/SNPassoc and/or use install_github('isglobal-brge/SNPassoc') to install the function and uncomment the function code.

Usage

gl2sa(x, verbose = NULL, installed = FALSE)

Arguments

x Name of the genlight object containing the SNP data [required].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].
installed Switch to run the function once SNPassoc package is installed [default FALSE].

Value

Returns an object of class ‘snp’ to be used with SNPassoc.
Author(s)

Bernd Guber (Post to https://groups.google.com/d/forum/dartr)

References

gl2sfs

Conversts a genlight object into a sfs input file

Description

The output of this function is suitable for analysis in fastsimcoal2 or dada.

Usage

```r
gl2sfs(
  x,
  n.invariant.tags = 0,
  outfile_root = "gl2sfs",
  outpath = tempdir(),
  verbose = NULL
)
```

Arguments

- **x**
  Name of the genlight object containing the SNP data [required].
- **n.invariant.tags**
  Number of invariant sites [default 0].
- **outfile_root**
  The root of the name of the output file [default "gl2sfs"].
- **outpath**
  Path where to save the output file [default tempdir()].
- **verbose**
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2, unless specified using gl.set.verbosity].

Details

It saves a derived sfs, assuming that the reference allele is the ancestral, and a MAF sfs.

At this stage this function caters only for diploid organisms, for samples from one population only, and for genotypes without missing data. Note that sfs uses frequencies considered independent, data are assumed to be from independent (i.e. not linked) loci. This means that only one site per tag should be considered (i.e. secondaries should be removed). If no monomorphic site estimates is provided (with `n.invariant.tags`), the sfs will only include the number of monomorphic sites in the data (but this will be a biased estimates as it doesn’t take into account the invariant tags that have not been included. This will affect parameter estimates in the analyses). Note that the number
of invariant tags can be estimated with gl.report.secondaries. In a limited number of cases, ascertainment bias can be explicitly modelled in fastsimcoal2. See fastsimcoal2 manual for details. It expects a dartR formatted genlight object, but it should also work with other genlight objects.

Value

A list with two elements: the DAF and MAF.

Author(s)

Custodian: Carlo Pacioni (Post to https://groups.google.com/d/forum/dartr)

References

---

**gl2shp**

Converts a genlight object to ESRI shapefiles or kml files

**Description**

This function exports coordinates in a genlight object to a point shape file (including also individual meta data if available). Coordinates are provided under x@other$latlon and assumed to be in WGS84 coordinates, if not proj4 string is provided.

**Usage**

```r
gl2shp(
  x,
  type = "shp",
  proj4 = "+proj=longlat +ellps=WGS84 +datum=WGS84 +no_defs",
  outfile = "gl",
  outpath = tempdir(),
  verbose = NULL
)
```

**Arguments**

- `x` Name of the genlight object containing the SNP data and location data, lat longs [required].
- `type` Type of output 'kml' or 'shp' [default 'shp'].
- `proj4` Proj4string of data set (see spatialreference.org for projections) [default WGS84].
outfile

Name (path) of the output shape file [default 'gl']. shp extension is added automatically.

outpath

Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.

verbose

Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Value

returns a SpatVector file

Author(s)

Bernd Guber (Post to https://groups.google.com/d/forum/dartr)

Examples

out <- gl2shp(testset.gl)

---

**gl2snapp**

Converts a genlight object to nexus format suitable for phylogenetic analysis by SNAPP (via BEAUi)

Description

The output nexus file contains the SNP data and relevant PAUP command lines suitable for BEAUi.

Usage

`gl2snapp(x, outfile = "snapp.nex", outpath = tempdir(), verbose = NULL)`

Arguments

- **x**
  Name of the genlight object containing the SNP data [required].
- **outfile**
  File name of the output file (including extension) [default "snapp.nex"].
- **outpath**
  Path where to save the output file [default tempdir(), mandated by CRAN]. Use outpath=getwd() or outpath='.' when calling this function to direct output files to your working directory.
- **verbose**
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Author(s)

Custodian: Arthur Georges (Post to https://groups.google.com/d/forum/dartr)
References

Examples

gl2snapp(testset.gl)

---

**gl2structure**

Converts a genlight object to STRUCTURE formated files

**Description**

This function exports genlight objects to STRUCTURE formatted files (be aware there is a gl2faststructure version as well). It is based on the code provided by Lindsay Clark (see [https://github.com/lvclark/R_genetics_conv](https://github.com/lvclark/R_genetics_conv)) and this function is basically a wrapper around her numeric2structure function. See also: Lindsay Clark. (2017, August 22). lvclark/R_genetics_conv: R_genetics_conv 1.1 (Version v1.1). Zenodo: doi.org/10.5281/zenodo.846816.

**Usage**

```r
gl2structure(
  x, 
  indNames = NULL, 
  addcolumns = NULL, 
  ploidy = 2, 
  exportMarkerNames = TRUE, 
  outfile = "gl.str", 
  outpath = tempdir(), 
  verbose = NULL 
)
```

**Arguments**

- **x** Name of the genlight object containing the SNP data and location data, lat longs [required].
- **indNames** Specify individuals names to be added [if NULL, defaults to indNames(x)].
- **addcolumns** Additional columns to be added before genotypes [default NULL].
- **ploidy** Set the ploidy [defaults 2].
- **exportMarkerNames** If TRUE, locus names locNames(x) will be included [default TRUE].
- **outfile** File name of the output file (including extension) [default "gl.str"].
- **outpath** Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
gl2svdquartets

Converts a genlight object to nexus format PAUP SVDquartets

Description

The output nexus file contains the SNP data in one of two forms, depending upon what you regard as most appropriate. One form, that used by Chifman and Kubatko, has two lines per individual, one providing the reference SNP the second providing the alternate SNP (method=1).

Usage

```r
gl2svdquartets(
  x,
  outfile = "svd.nex",
  outpath = tempdir(),
  method = 2,
  verbose = NULL
)
```

Arguments

- **x** Name of the genlight object containing the SNP data or tag P/A data [required].
- **outfile** File name of the output file (including extension) [default 'svd.nex'].
- **outpath** Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` when calling this function or `set.tempdir <- getwd()` elsewhere in your script to direct output files to your working directory.
- **method** Method = 1, nexus file with two lines per individual; method = 2, nexus file with one line per individual, ambiguity codes for SNP genotypes, 0 or 1 for presence/absence data [default 2].
- **verbose** Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

Author(s)

Bernd Gruber (wrapper) and Lindsay V. Clark [lvclark@illinois.edu]
Details

A second form, recommended by Dave Swoford, has a single line per individual, resolving heterozygous SNPs by replacing them with standard ambiguity codes (method = 2).
If the data are tag presence/absence, then method = 2 is assumed.

`gl2treemix`  
Converts a genlight object to a treemix input file

Description

The output file contains the SNP data in the format expected by treemix – see the treemix manual. The file will be gzipped before in order to be recognised by treemix. Plotting functions provided with treemix will need to be sourced from the treemix download page.

Usage

```r
gl2treemix(
  x,
  outfile = "treemix_input.gz",
  outpath = tempdir(),
  verbose = NULL
)
```

Arguments

- `x`  
  Name of the genlight object containing the SNP data [required].
- `outfile`  
  File name of the output file (including gz extension) [default ‘treemix_input.gz’].
- `outpath`  
  Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath = getwd()` when calling this function or `set.tempdir <- getwd()` elsewhere in your script to direct output files to your working directory.
- `verbose`  
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using `gl.set.verbosity`].

### gl2vcf

*Converts a genlight object into vcf format*

**Description**

This function exports a genlight object into VCF format and save it into a file.

**Usage**

```r
gl2vcf(
  x,
  plink_path = getwd(),
  outfile = "gl_vcf",
  outpath = tempdir(),
  snp_pos = "0",
  snp_chr = "0",
  chr_format = "character",
  pos_cM = "0",
  ID_dad = "0",
  ID_mom = "0",
  sex_code = "unknown",
  phen_value = "0",
  verbose = NULL
)
```

**Arguments**

- `x`: Name of the genlight object containing the SNP data [required].
- `plink_path`: Path of PLINK binary file [default getwd()].
- `outfile`: File name of the output file [default 'gl_vcf'].
- `outpath`: Path where to save the output file [default tempdir(), mandated by CRAN]. Use `outpath=getwd()` or `outpath='.'` when calling this function to direct output files to your working directory.
### Fields

- **snp_pos**: Field name from the slot loc.metrics where the SNP position is stored [default '0'].
- **snp_chr**: Field name from the slot loc.metrics where the chromosome of each is stored [default '0'].
- **chr_format**: Whether chromosome information is stored as 'numeric' or as 'character', see details [default 'character'].
- **pos_cM**: A vector, with as many elements as there are loci, containing the SNP position in morgans or centimorgans [default '0'].
- **ID_dad**: A vector, with as many elements as there are individuals, containing the ID of the father, '0' if father isn't in dataset [default '0'].
- **ID_mom**: A vector, with as many elements as there are individuals, containing the ID of the mother, '0' if mother isn't in dataset [default '0'].
- **sex_code**: A vector, with as many elements as there are individuals, containing the sex code ('male', 'female', 'unknown') [default 'unknown'].
- **phen_value**: A vector, with as many elements as there are individuals, containing the phenotype value. '1' = control, '2' = case, '0' = unknown [default '0'].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

### Details

This function requires to download the binary file of PLINK 1.9 and provide its path (plink_path). The binary file can be downloaded from: https://www.cog-genomics.org/plink/

The chromosome information for unmapped SNPS is coded as 0. Family ID is taken from x$pop Within-family ID (cannot be '0') is taken from indNames(x) Variant identifier is taken from locNames(x)

**is.fixed**  
*Tests if two populations are fixed at a given locus*

**Description**
This script compares two percent allele frequencies and reports TRUE if they represent a fixed difference, FALSE otherwise.

**Usage**

```r
is.fixed(s1, s2, tloc = 0)
```
Arguments

s1  Percentage SNP allele or sequence tag frequency for the first population [required].
s2  Percentage SNP allele or sequence tag frequency for the second population [required].
tloc Threshold value for tolerance in when a difference is regarded as fixed [default 0].

Details

A fixed difference at a locus occurs when two populations share no alleles, noting that SNPs are biallelic (ploidy=2). Tolerance in the definition of a fixed difference is provided by the t parameter. For example, t=0.05 means that SNP allele frequencies of 95.5 and 5.95 percent will be reported as fixed (TRUE).

Value

TRUE (fixed difference) or FALSE (alleles shared) or NA (one or both s1 or s2 missing)

theme_dartR

**Description**

This is the theme used as default for dartR plots. This function controls all non-data display elements in the plots.

**Usage**

```r
theme_dartR(
  base_size = 11,
  base_family = "",
  base_line_size = base_size/22,
  base_rect_size = base_size/22
)
```

**Arguments**

- `base_size`: base font size, given in pts.
- `base_family`: base font family
- `base_line_size`: base size for line elements
- `base_rect_size`: base size for rect elements

**Examples**

```r
# ggplot(data.frame(dummy=rnorm(1000)),aes(dummy)) +
# geom_histogram(binwidth=0.1) + theme_dartR()
```

utils.basic.stats

*Calculates mean observed heterozygosity, mean expected heterozygosity and Fis per locus, per population and Fst across all populations*

**Description**

This is a re-implementation of `hierfstat::basics.stats` specifically for genlight objects. Formula (and hence results) match exactly the original version of `hierfstat::basics.stats` (although Dstp and Fstp are not currently computed) but it is much faster.

**Usage**

```r
utils.basic.stats(x)
```
Arguments

- **x**: A genlight object containing the SNP genotypes [required].

Value

A list with the statistics for each population

Author(s)

Luis Mijangos and Carlo Pacioni (bugs? Post to https://groups.google.com/d/forum/dartr)

Examples

```r
out <- utils.basic.stats(platypus.gl)
```

---

**utils.check.datatype**  
**Utility function to check the class of an object passed to a function**

Description

Most functions require access to a genlight object, dist matrix, data matrix or fixed difference list (fd), and this function checks that a genlight object or one of the above has been passed, whether the genlight object is a SNP dataset or a SilicoDArT object, and reports back if verbosity is >=2.

Usage

```r
utils.check.datatype(
  x,
  accept = c("genlight", "SNP", "SilicoDArT"),
  verbose = NULL
)
```

Arguments

- **x**: Name of the genlight object, dist matrix, data matrix, glPCA, or fixed difference list (fd) [required].
- **accept**: Vector containing the classes of objects that are to be accepted [default c(’genlight’, ’SNP’, ’SilicoDArT’)].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL, unless specified using gl.set.verbosity].

Details

This function checks the class of passed object and sets the datatype to ’SNP’, ’SilicoDArT’, ’dist’, ’mat’, or class[1](x) as appropriate.

Note also that this function checks to see if there are individuals or loci scored as all missing (NA) and if so, issues the user with a warning.

Note: One and only one of gl.check, fd.check, dist.check or mat.check can be TRUE.
Value

datatype, 'SNP' for SNP data, 'SilicoDArT' for P/A data, 'dist' for a distance matrix, 'mat' for a data matrix, 'glPCA' for an ordination file, or class(x)[1].

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

datatype <- utils.check.datatype(testset.gl)
datatype <- utils.check.datatype(as.matrix(testset.gl), accept='matrix')
fd <- gl.fixed.diff(testset.gl)
datatype <- utils.check.datatype(fd, accept='fd')

utils.dart2genlight  Converts DarT to genlight

Description

Converts a DArT file (read via read.dart) into a genlight object adegenet. Internal function called by gl.read.dart

Usage

utils.dart2genlight(
  dart,
  ind.metafile = NULL,
  covfilename = NULL,
  probar = TRUE,
  verbose = NULL
)

Arguments

dart A dart object created via read.dart [required].
ind.metafile Optional file in csv format with metadata for each individual (see details for explanation) [default NULL].
covfilename Deprecated, use parameter ind.metafile.
probar Show progress bar [default TRUE].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL].
Details

The ind.metadata file needs to have very specific headings. First a heading called id. Here the ids have to match the ids in the dart object colnames(dart[[4]]). The following column headings are optional. pop: specifies the population membership of each individual. lat and lon specify spatial coordinates (in decimal degrees WGS1984 format). Additional columns with individual metadata can be imported (e.g. age, gender).

Value

A genlight object. Including all available slots are filled. loc.names, ind.names, pop, lat, lon (if provided via the ind.metadata file)

utils.dist.binary

Calculates a distance matrix for individuals defined in a dartR genlight object using binary P/A data (SilicoDArT)

Description

This script calculates various distances between individuals based on sequence tag Presence/Absence data.

Usage

utils.dist.binary(
  x,
  method = "simple",
  scale = FALSE,
  swap = FALSE,
  output = "dist",
  verbose = NULL
)

Arguments

x
  Name of the genlight containing the genotypes [required].
method
  Specify distance measure [default simple].
scale
  If TRUE and method=’euclidean’, the distance will be scaled to fall in the range [0,1] [default FALSE].
swap
  If TRUE and working with presence-absence data, then presence (no disrupting mutation) is scored as 0 and absence (presence of a disrupting mutation) is scored as 1 [default FALSE].
output
  Specify the format and class of the object to be returned, dist for a object of class dist, matrix for an object of class matrix [default "dist"].
verbose
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].
Details

The distance measure can be one of:

- **Euclidean** – Euclidean Distance applied to cartesian coordinates defined by the loci, scored as 0 or 1. Presence and absence equally weighted.
- **simple** – simple matching, both 1 or both 0 = 0; one 1 and the other 0 = 1. Presence and absence equally weighted.
- **Jaccard** – ignores matching 0, both 1 = 0; one 1 and the other 0 = 1. Absences could be for different reasons.
- **Bray-Curtis** – both 0 = 0; both 1 = 2; one 1 and the other 0 = 1. Absences could be for different reasons. Sometimes called the Dice or Sorensen distance.

One might choose to disregard or downweight absences in comparison with presences because the homology of absences is less clear (mutation at one or the other, or both restriction sites). Your call.

Value

An object of class ’dist’ or ’matrix’ giving distances between individuals

Author(s)

Examples

```r
D <- utils.dist.binary(testset.gs, method='Jaccard')
D <- utils.dist.binary(testset.gs, method='Simple')
D <- utils.dist.binary(testset.gs, method='Euclidean', scale=TRUE)
```

---

`utils.dist.ind.snp` *Calculates a distance matrix for individuals defined in a dartR genlight object using SNP data (DArTseq)*

Description

This script calculates various distances between individuals based on SNP genotypes.

Usage

```r
utils.dist.ind.snp(
  x,
  method = "Euclidean",
  scale = FALSE,
  output = "dist",
  verbose = NULL
)
```
Arguments

- **x**: Name of the genlight containing the genotypes [required].
- **method**: Specify distance measure [default Euclidean].
- **scale**: If TRUE and method='Euclidean', the distance will be scaled to fall in the range [0,1] [default FALSE].
- **output**: Specify the format and class of the object to be returned, dist for a object of class dist, matrix for an object of class matrix [default "dist"].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

Details

The distance measure can be one of:

- Euclidean – Euclidean Distance applied to Cartesian coordinates defined by the loci, scored as 0, 1 or 2.
- Simple – simple mismatch, 0 where no alleles are shared, 1 where one allele is shared, 2 where both alleles are shared.
- Absolute – absolute mismatch, 0 where no alleles are shared, 1 where one or both alleles are shared.
- Czekanowski (or Manhattan) calculates the city block metric distance by summing the scores on each axis (locus).

Value

An object of class 'dist' or 'matrix' giving distances between individuals

Author(s)

Author(s): Arthur Georges. Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr

Examples

```r
D <- utils.dist.ind.snp(testset.gl, method='Manhattan')
D <- utils.dist.ind.snp(testset.gl, method='Simple')
D <- utils.dist.ind.snp(testset.gl, method='Euclidean',scale=TRUE)
```
A utility script to flag the start of a script

Usage

utils.flag.start(func = NULL, build = NULL, verbosity = NULL)

Arguments

func Name of the function that is starting [required].
built Name of the build [default NULL].
verbosity Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress
and results summary; 5, full report [default 2].

Value
calling function name

Author(s)

Custodian: Arthur Georges – Post to https://groups.google.com/d/forum/dartr @export

Calculates the Hamming distance between two DArT trimmed DNA sequences

Description

Hamming distance is calculated as the number of base differences between two sequences which can
be expressed as a count or a proportion. Typically, it is calculated between two sequences of equal
length. In the context of DArT trimmed sequences, which differ in length but which are anchored
to the left by the restriction enzyme recognition sequence, it is sensible to compare the two trimmed
sequences starting from immediately after the common recognition sequence and terminating at the
last base of the shorter sequence.

Usage

utils.hamming(str1, str2, r = 4)
Arguments

str1  String containing the first sequence [required].
str2  String containing the second sequence [required].
r    Number of bases in the restriction enzyme recognition sequence [default 4].

Details

The Hamming distance between the rows of a matrix can be computed quickly by exploiting the fact that the dot product of two binary vectors $x$ and $(1-y)$ counts the corresponding elements that are different between $x$ and $y$. This matrix multiplication can also be used for matrices with more than two possible values, and different types of elements, such as DNA sequences.

The function calculates the Hamming distance between all columns of a matrix $X$, or two matrices $X$ and $Y$. Again matrix multiplication is used, this time for counting, between two columns $x$ and $y$, the number of cases in which corresponding elements have the same value (e.g. A, C, G or T). This counting is done for each of the possible values individually, while iteratively adding the results. The end result of the iterative adding is the sum of all corresponding elements that are the same, i.e. the inverse of the Hamming distance. Therefore, the last step is to subtract this end result $H$ from the maximum possible distance, which is the number of rows of matrix $X$.

If the two DNA sequences are of differing length, the longer is truncated. The initial common restriction enzyme recognition sequence is ignored.

The algorithm is that of Johann de Jong [https://johanndejong.wordpress.com/2015/10/02/faster-hamming-distance-in-r-2/](https://johanndejong.wordpress.com/2015/10/02/faster-hamming-distance-in-r-2/)

Value

Hamming distance between the two strings

Author(s)

Custodian: Arthur Georges (Post to [https://groups.google.com/d/forum/dartr](https://groups.google.com/d/forum/dartr))

---

**utils.het.pop**

*Calculates expected mean expected heterozygosity per population*

Description

Calculates expected mean expected heterozygosity per population

Usage

```
utils.het.pop(x)
```

Arguments

x  A genlight object containing the SNP genotypes [required].
Value

A vector with the mean expected heterozygosity for each population

Author(s)

Bernd Gruber & Luis Mijangos (bugs? Post to https://groups.google.com/d/forum/dartr)

Examples

out <- utils.het.pop(testset.gl)

**utils.jackknife**  
*Conducts jackknife resampling using a genlight object*

Description

Jackknife resampling is a statistical procedure where for a dataset of sample size \( n \), subsamples of size \( n-1 \) are used to compute a statistic. The collection of the values obtained can be used to evaluate the variability around the point estimate. This function can take the loci, the individuals or the populations as units over which to conduct resampling.

**bold** Note that when \( n \) is very small, jackknife resampling is not recommended.

Parallel computation is implemented. The argument `n.cores` indicates the number of cores to use. If "auto" [default], it will use all but one available cores. If the number of units is small (e.g. a few populations), there is not real advantage in using parallel computation. On the other hand, if the number of units is large (e.g. thousands of loci), even with parallel computation, this function can be very slow.

Usage

```r
utils.jackknife(
  x,  
  FUN,  
  unit = "loc",  
  recalc = FALSE,  
  mono.rm = FALSE,  
  n.cores = "auto",  
  verbose = NULL,  
  ...
)
```

Arguments

- **x**  
  Name of the genlight object containing SNP genotypes [required].
- **FUN**  
  The name of the function to be used to calculate the statistic
- **unit**  
  The unit to use for resampling. One of c("loc", "ind", "pop"): loci, individuals or populations
**utils.n.var.invariant**

Recalculate the locus metadata statistics [default FALSE].

**mono.rm**
Remove monomorphic loci [default FALSE].

**n.cores**
The number of cores to use. If "auto" [default], it will use all but one available cores.

**verbose**
Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2 or as specified using gl.set.verbosity].

... any additional arguments to be passed to FUN

**Value**
A list of length n where each element is the output of FUN

**Author(s)**
Custodian: Carlo Pacioni – Post to https://groups.google.com/d/forum/dartr

**Examples**

```r
platMod.gl <- gl.filter.allna(platypus.gl)
chk.pop <- utils.jackknife(x=platMod.gl, FUN="gl.alf", unit="pop",
recalc = FALSE, mono.rm = FALSE, n.cores = 1, verbose=0)
```

**Description**
Calculate the number of variant and invariant sites by locus and add them as columns in loc.metrics. This can be useful to conduct further filtering, for example where only loci with secondaries are wanted for phylogenetic analyses.

**Usage**

```r
utils.n.var.invariant(x, verbose = NULL)
```

**Arguments**

- **x**
  Name of the genlight object containing the SNP data [required].

- **verbose**
  Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL].
Details

Invariant sites are the sites (nucleotide) that are not polymorphic. When the locus metadata supplied by DArT includes the sequence of the allele (TrimmedSequence), it is used by this function to estimate the number of sites that were sequenced in each tag (read). This script then subtracts the number of polymorphic sites. The length of the trimmed sequence (lenTrimSeq), the number of variant (n.variant) and invariant (n.invariant) sites are the added to the table in gl@others$loc.metrics.

NOTE: It is important to realise that this function correctly estimates the number of variant and invariant sites only when it is executed on genlight objects before secondaries are removed.

Value

The modified genlight object.

Author(s)

Carlo Pacioni (Post to https://groups.google.com/d/forum/dartr)

See Also

gl.filter.secondaries, gl.report.heterozygosity

Examples

```r
out <- utils.n.var.invariant(platypus.gl)
```

---

**OutFLANK: An Fst outlier approach by Mike Whitlock and Katie Lotterhos, University of British Columbia.**

Description

This function is the original implementation of Outflank by Whitlock and Lotterhos. dartR simply provides a convenient wrapper around their functions and an easier install being an r package (for information please refer to their github repository)

Usage

```r
utils.outflank(  
  FstDataFrame,  
  LeftTrimFraction = 0.05,  
  RightTrimFraction = 0.05,  
  Hmin = 0.1,  
  NumberOfSamples,  
  qthreshold = 0.05
)
```
Arguments

FstDataFrame  A data frame that includes a row for each locus, with columns as follows:

• $LocusName: a character string that uniquely names each locus.
• $FST: Fst calculated for this locus. (Kept here to report the unbased Fst of the results)
• $T1: The numerator of the estimator for Fst (necessary, with $T2, to calculate mean Fst)
• $T2: The denominator of the estimator of Fst
• $FSTNoCorr: Fst calculated for this locus without sample size correction. (Used to find outliers)
• $T1NoCorr: The numerator of the estimator for Fst without sample size correction (necessary, with $T2, to calculate mean Fst)
• $T2NoCorr: The denominator of the estimator of Fst without sample size correction
• $He: The heterozygosity of the locus (used to screen out low heterozygosity loci that have a different distribution)

LeftTrimFraction  The proportion of loci that are trimmed from the lower end of the range of Fst before the likelihood function is applied [default 0.05].

RightTrimFraction  The proportion of loci that are trimmed from the upper end of the range of Fst before the likelihood function is applied [default 0.05].

Hmin  The minimum heterozygosity required before including calculations from a locus [default 0.1].

NumberOfSamples  The number of spatial locations included in the data set.

qthreshold  The desired false discovery rate threshold for calculating q-values [default 0.05].

Details

This method looks for Fst outliers from a list of Fst’s for different loci. It assumes that each locus has been genotyped in all populations with approximately equal coverage.

OutFLANK estimates the distribution of Fst based on a trimmed sample of Fst’s. It assumes that the majority of loci in the center of the distribution are neutral and infers the shape of the distribution of neutral Fst using a trimmed set of loci. Loci with the highest and lowest Fst’s are trimmed from the data set before this inference, and the distribution of Fst df/(mean Fst) is assumed to follow a chi-square distribution. Based on this inferred distribution, each locus is given a q-value based on its quantile in the inferred null distribution.

The main procedure is called OutFLANK – see comments in that function immediately below for input and output formats. The other functions here are necessary and must be uploaded, but are not necessarily needed by the user directly.

Steps:
Value

The function returns a list with seven elements:

- $FSTbar$: the mean $FST$ inferred from loci not marked as outliers
- $FSTNoCorrbar$: the mean $FST$ (not corrected for sample size - gives an upwardly biased estimate of $FST$)
- $dfInferred$: the inferred number of degrees of freedom for the chi-square distribution of neutral $FST$
- $numberLowFstOutliers$: Number of loci flagged as having a significantly low $FST$ (not reliable)
- $numberHighFstOutliers$: Number of loci identified as having significantly high $FST$
- $results$: a data frame with a row for each locus. This data frame includes all the original columns in the data set, and six new ones:
  - $indexOrder$ (the original order of the input data set),
  - $GoodH$ (Boolean variable which is TRUE if the expected heterozygosity is greater than the Hemin set by input),
  - $OutlierFlag$ (TRUE if the method identifies the locus as an outlier, FALSE otherwise), and
  - $q$ (the $q$-value for the test of neutrality for the locus)
  - $pvalues$ (the $p$-value for the test of neutrality for the locus)
  - $pvaluesRightTail$ the one-sided (right tail) $p$-value for a locus

Author(s)

Bernd Gruber (bugs? Post to https://groups.google.com/d/forum/dartr); original implementation of Whitlock & Lotterhos
Args

SNPmat

This is an array of genotypes with a row for each individual. There should be a column for each SNP, with the number of copies of the focal allele (0, 1, or 2) for that individual. If that individual is missing data for that SNP, there should be a 9, instead.

locusNames

A list of names for each SNP locus. There should be the same number of locus names as there are columns in SNPmat.

popNames

A list of population names to give location for each individual. Typically multiple individuals will have the same popName. The list popNames should have the same length as the number of rows in SNPmat.

Value

Returns a data frame in the form needed for the main OutFLANK function.

Description

This function takes the output of OutFLANK as input with the OFoutput parameter. It plots a histogram of the FST (by default, the uncorrected FSTs used by OutFLANK) of loci and overlays the inferred null histogram.

Usage

utils.outflank.plotter(
  OFoutput,
  withOutliers = TRUE,
  NoCorr = TRUE,
  Hmin = 0.1,
  binwidth = 0.005,
  Zoom = FALSE,
  RightZoomFraction = 0.05,
  titletext = NULL
)

Arguments

OFoutput

The output of the function OutFLANK()

withOutliers

Determines whether the loci marked as outliers (with $OutlierFlag) are included in the histogram.

NoCorr

Plots the distribution of FSTNoCorr when TRUE. Recommended, because this is the data used by OutFLANK to infer the distribution.
**utils.read.dart**

The minimum heterozygosity required before including a locus in the plot.

The width of bins in the histogram.

If Zoom is set to TRUE, then the graph will zoom in on the right tail of the distribution (based on argument RightZoomFraction).

Used when Zoom = TRUE. Defines the proportion of the distribution to plot.

Allows a test string to be printed as a title on the graph.

**Value**

produces a histogram of the FST

---

**Imports DarT data to R**

**Description**

Internal function called by gl.read.dart

**Usage**

```r
utils.read.dart(
    filename,
    nas = "-",
    topskip = NULL,
    lastmetric = "RepAvg",
    service_row = 1,
    plate_row = 3,
    verbose = NULL
)
```

**Arguments**

<table>
<thead>
<tr>
<th>Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>filename</td>
<td>Path to file (csv file only currently) [required].</td>
</tr>
<tr>
<td>nas</td>
<td>A character specifying NAs [default <code>-</code>].</td>
</tr>
<tr>
<td>topskip</td>
<td>A number specifying the number of rows to be skipped. If not provided the number of rows to be skipped are 'guessed' by the number of rows with '*' at the beginning [default NULL].</td>
</tr>
<tr>
<td>lastmetric</td>
<td>Specifies the last non genetic column [default 'RepAvg']. Be sure to check if that is true, otherwise the number of individuals will not match. You can also specify the last column by a number.</td>
</tr>
<tr>
<td>service_row</td>
<td>The row number in which the information of the DArT service is contained [default 1].</td>
</tr>
<tr>
<td>plate_row</td>
<td>The row number in which the information of the plate location is contained [default 3].</td>
</tr>
<tr>
<td>verbose</td>
<td>Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log ; 3, progress and results summary; 5, full report [default NULL].</td>
</tr>
</tbody>
</table>
Value

A list of length 5. #dart format (one or two rows) #individuals, #snps, #non genetic metrics, #genetic
data (still two line format, rows=snps, columns=individuals)

Description

The locus metadata supplied by DArT has OneRatioRef, OneRatioSnp, PICRef, PICSnp, and AvgPIC included, but the allelic composition will change when some individuals, or populations, are removed from the dataset and so the initial statistics will no longer apply. This script recalculates these statistics and places the recalculated values in the appropriate place in the genlight object.

Usage

utils.recalc.avgpic(x, verbose = NULL)

Arguments

x Name of the genlight object containing the SNP data [required].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

Details

If the locus metadata OneRatioRefSnp, PICRefSnp and/or AvgPIC do not exist, the script creates and populates them.

Value

The modified genlight object.

utils.recalc.metrics for recalculating all metrics, utils.recalc.callrate for recalculating CallRate, utils.recalc.freqhomref for recalculating frequency of homozygous reference, utils.recalc.freqhomsnp for recalculating frequency of homozygous alternate, utils.recalc.frequhet for recalculating frequency of heterozygotes, gl.recalc.maf for recalculating minor allele frequency, gl.recalc.rdepth for recalculating average read depth
**utils.recalc.callrate**

A utility script to recalculate the callrate by locus after some populations have been deleted

**Description**

SNP datasets generated by DArT have missing values primarily arising from failure to call a SNP because of a mutation at one or both of the restriction enzyme recognition sites. The locus metadata supplied by DArT has callrate included, but the call rate will change when some individuals are removed from the dataset. This script recalculates the callrate and places these recalculated values in the appropriate place in the genlight object. It sets the Call Rate flag to TRUE.

**Usage**

```r
utils.recalc.callrate(x, verbose = NULL)
```

**Arguments**

- `x`: Name of the genlight object containing the SNP data [required].
- `verbose`: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

**Value**

The modified genlight object

- `utils.recalc.freqhet` for recalculating frequency of heterozygotes
- `gl.recalc.maf` for recalculating minor allele frequency
- `gl.recalc.rdepth` for recalculating average read depth

**Examples**

```r
#out <- utils.recalc.callrate(testset.gl)
```
A utility script to recalculate the frequency of the heterozygous SNPs by locus after some populations have been deleted

Description

The locus metadata supplied by DArT has FreqHets included, but the frequency of the heterozygotes will change when some individuals are removed from the dataset.

Usage

```r
utils.recalc.freqhets(x, verbose = NULL)
```

Arguments

- `x` Name of the genlight object containing the SNP data [required].
- `verbose` Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

Details

This script recalculates the FreqHets and places these recalculated values in the appropriate place in the genlight object.

Note that the frequency of the homozygote reference SNPS is calculated from the individuals that could be scored.

Value

The modified genlight object.

- `gl.recalc.rdepth` for recalculating average read depth

Examples

```r
#out <- utils.recalc.freqhets(testset.gl)
```
utils.recalc.freqhomref

A utility script to recalculate the frequency of the homozygous reference SNP by locus after some populations have been deleted

Description

The locus metadata supplied by DArT has FreqHomRef included, but the frequency of the homozygous reference will change when some individuals are removed from the dataset.

Usage

utils.recalc.freqhomref(x, verbose = NULL)

Arguments

x Name of the genlight object containing the SNP data [required].

verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

Details

This script recalculates the FreqHomRef and places these recalculated values in the appropriate place in the genlight object.

Note that the frequency of the homozygote reference SNPS is calculated from the individuals that could be scored.

Value

The modified genlight object

Examples

#result <- utils.recalc.freqhomref(testset.gl)
utils.recalc.freqhomsnp

A utility script to recalculate the frequency of the homozygous alternate SNP by locus after some populations have been deleted

Description

The locus metadata supplied by DArT has FreqHomSnps included, but the frequency of the homozygous alternate will change when some individuals are removed from the dataset.

Usage

utils.recalc.freqhomsnp(x, verbose = NULL)

Arguments

x Name of the genlight object containing the SNP data [required].
verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

Details

This script recalculates the FreqHomSnps and places these recalculated values in the appropriate place in the genlight object.

Note that the frequency of the homozygote alternate SNPS is calculated from the individuals that could be scored.

Value

The modified genlight object.

Examples

#out <- utils.recalc.freqhomsnp(testset.gl)
A utility script to recalculate the minor allele frequency by locus, typically after some populations have been deleted

Description

The locus metadata supplied by DArT does not have MAF included, so it is calculated and added to the locus.metadata by this script. The minimum allele frequency will change when some individuals are removed from the dataset. This script recalculates the MAF and places these recalculated values in the appropriate place in the genlight object.

Usage

utils.recalc.maf(x, verbose = NULL)

Arguments

x Name of the genlight object containing the SNP data [required].

verbose Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default 2].

Value

The modified genlight dataset.

Author(s)

Custodian: Luis Mijangos (Post to https://groups.google.com/d/forum/dartr)

See Also

utils.recalc.metrics for recalculating all metrics, utils.recalc.callrate for recalculating CallRate, utils.recalc.freqhomref for recalculating frequency of homozygous reference, utils.recalc.freqhomsnp for recalculating frequency of homozygous alternate, utils.recalc.freqhet for recalculating frequency of heterozygotes, gl.recalc.avgpic for recalculating AvgPIC, gl.recalc.rdepth for recalculating average read depth

Examples

#f <- dartR::utils.recalc.maf(testset.gl)
A utility script to reset to FALSE (or TRUE) the locus metric flags after some individuals or populations have been deleted.

Description

The locus metadata supplied by DArT has OneRatioRef, OneRatioSnp, PICRef, PICSnp, and Avg-PIC included, but the allelic composition will change when some individuals are removed from the dataset and so the initial statistics will no longer apply. This applies also to some variable calculated by dartR (e.g. maf). This script resets the locus metrics flags to FALSE to indicate that these statistics in the genlight object are no longer current. The verbosity default is also set, and in the case of SilicoDArT, the flags PIC and OneRatio are also set.

Usage

```r
utils.reset.flags(x, set = FALSE, value = 2, verbose = NULL)
```

Arguments

- **x**: Name of the genlight object containing the SNP data or tag presence/absence data (SilicoDArT) [required].
- **set**: Set the flags to TRUE or FALSE [default FALSE].
- **value**: Set the default verbosity for all functions, where verbosity is not specified [default 2].
- **verbose**: Verbosity: 0, silent or fatal errors; 1, begin and end; 2, progress log; 3, progress and results summary; 5, full report [default NULL].

Details

If the locus metrics do not exist then they are added to the genlight object but not populated. If the locus metrics flags do not exist, then they are added to the genlight object and set to FALSE (or TRUE).

Value

The modified genlight object

utils.structure.run  Utility function to run structure

Description

These functions were copied from package strataG, which is no longer on CRAN (maintained by Eric Archer)

Usage

```r
utils.structure.run(
  g,
  k.range = NULL,
  num.k.rep = 1,
  label = NULL,
  delete.files = TRUE,
  exec = "structure",
  ...
)
```

Arguments

- `g`: a gtypes object [see strataG].
- `k.range`: vector of values to for maxpop in multiple runs. If set to `NULL`, a single STRUCTURE run is conducted with maxpops groups. If specified, do not also specify maxpops.
- `num.k.rep`: number of replicates for each value in `k.range`.
- `label`: label to use for input and output files
- `delete.files`: logical. Delete all files when STRUCTURE is finished?
- `exec`: name of executable for STRUCTURE. Defaults to "structure".
- `...`: arguments to be passed to structureWrite.

Value

- `structureRun`: a list where each element is a list with results from structureRead and a vector of the filenames used
- `structureWrite`: a vector of the filenames used by STRUCTURE
- `structureRead`: a list containing:
  - `summary`: new locus name, which is a combination of loci in group
  - `q.mat`: data.frame of assignment probabilities for each id
prior.anc list of prior ancestry estimates for each individual where population priors were used
files vector of input and output files used by STRUCTURE
label label for the run
