Package ‘vroom’

September 30, 2020

Title  Read and Write Rectangular Text Data Quickly

Version  1.3.2

Description  The goal of 'vroom' is to read and write data (like 'csv', 'tsv' and 'fwf') quickly. When reading it uses a quick initial indexing step, then reads the values lazily, so only the data you actually use needs to be read. The writer formats the data in parallel and writes to disk asynchronously from formatting.

Index  23
Create column specification

Description

cols() includes all columns in the input data, guessing the column types as the default. cols_only() includes only the columns you explicitly specify, skipping the rest.

Usage

cols(..., .default = col_guess(), .delim = NULL)
cols_only(...)
col_logical(...)
col_integer(...)
col_big_integer(...)
col_double(...)
col_character(...)
col_skip(...)
col_number(...)
col_guess(...)
col_factor(levels = NULL, ordered = FALSE, include_na = FALSE, ...)
col_datetime(format = "", ...)
col_date(format = "", ...)
col_time(format = "", ...)

Arguments

... Either column objects created by col_*( ), or their abbreviated character names (as described in the col_types argument of vroom() ). If you’re only overriding a few columns, it’s best to refer to columns by name. If not named, the column types must match the column names exactly. In col_*( ) functions these are stored in the object.

.default Any named columns not explicitly overridden in ... will be read with this column type.

.delim The delimiter to use when parsing. If the delim argument used in the call to vroom() it takes precedence over the one specified in col_types.
levels: character vector providing set of allowed levels. If NULL, will generate levels based on the unique values of x, ordered by order of appearance in x.

ordered: Is it an ordered factor?

include_na: If NA are present, include as an explicit factor to level?

format: A format specification, as described below. If set to "", date times are parsed as ISO8601, dates and times used the date and time formats specified in the locale(). Unlike strptime(), the format specification must match the complete string.

Details

The available specifications are: (with string abbreviations in brackets)

• col_logical() [l], containing only T, F, TRUE or FALSE.
• col_integer() [i], integers.
• col_big_integer() [I], Big Integers (64bit), requires the bit64 package.
• col_double() [d], doubles.
• col_character() [c], everything else.
• col_factor(levels, ordered) [f], a fixed set of values.
• col_date(format = "") [D]: with the locale's date_format.
• col_time(format = "") [t]: with the locale's time_format.
• col_datetime(format = "") [T]: ISO8601 date times
• col_number() [n], numbers containing the grouping_mark
• col_skip() [_, -], don't import this column.
• col_guess() [?], parse using the "best" type based on the input.

Examples

```r
cols(a = col_integer())
cols_only(a = col_integer())

# You can also use the standard abbreviations
cols(a = "i")
cols(a = "i", b = "d", c = "_")

# You can also use multiple sets of column definitions by combining
# them like so:

t1 <- cols(
  column_one = col_integer(),
  column_two = col_number())

t2 <- cols(
  column_three = col_character())

t3 <- t1
t3$cols <- c(t1$cols, t2$cols)
t3
```
**cols_condense**

*Examine the column specifications for a data frame*

**Description**

`cols_condense()` takes a spec object and condenses its definition by setting the default column type to the most frequent type and only listing columns with a different type.

`spec()` extracts the full column specification from a tibble created by `readr`.

**Usage**

```r
cols_condense(x)

spec(x)
```

**Arguments**

- `x` The data frame object to extract from

**Value**

A `col_spec` object.

**Examples**

```r
df <- vroom(vroom_example("mtcars.csv"))
s <- spec(df)
s
cols_condense(s)
```

---

**date_names**

*Create or retrieve date names*

**Description**

When parsing dates, you often need to know how weekdays of the week and months are represented as text. This pair of functions allows you to either create your own, or retrieve from a standard list. The standard list is derived from ICU ([http://site.icu-project.org](http://site.icu-project.org)) via the `stringi` package.

**Usage**

```r
date_names(mon, mon_ab = mon, day, day_ab = day, am_pm = c("AM", "PM"))

date_names_lang(language)

date_names_langs()
```
Arguments

- mon, mon_ab: Full and abbreviated month names.
- day, day_ab: Full and abbreviated week day names. Starts with Sunday.
- am_pm: Names used for AM and PM.
- language: A BCP 47 locale, made up of a language and a region, e.g. "en_US" for American English. See date_names_lang() for a complete list of available locales.

Examples

date_names_lang("en")
date_names_lang("ko")
date_names_lang("fr")

Description

Generate individual vectors of the types supported by vroom

Usage

gen_character(n, min = 5, max = 25, values = c(letters, LETTERS, 0:9), ...)
gen_double(n, f = stats::rnorm, ...)
gen_number(n, f = stats::rnorm, ...)
gen_integer(n, min = 1L, max = .Machine$integer.max, prob = NULL, ...)
gen_factor(n, levels = NULL, ordered = FALSE, num_levels = gen_integer(1L, 1L, 25L), ...)
gen_time(n, min = 0, max = hms::hms(days = 1), fractional = FALSE, ...)
gen_date(n, min = as.Date("2001-01-01"), max = as.Date("2021-01-01"), ...)
gen_datetime(n, min = as.POSIXct("2001-01-01"), max = as.POSIXct("2021-01-01"), tz = "UTC", ...)
gen_tbl

\begin{verbatim}
gen_logical(n, ...)
gen_name(n)
\end{verbatim}

**Arguments**

- **n**  
The size of the vector to generate
- **min**  
The minimum range for the vector
- **max**  
The maximum range for the vector
- **values**  
The explicit values to use.
- **...**  
Additional arguments passed to internal generation functions
- **f**  
The random function to use.
- **prob**  
a vector of probability weights for obtaining the elements of the vector being sampled.
- **levels**  
The explicit levels to use, if NULL random levels are generated using \texttt{gen_name()}.
- **ordered**  
Should the factors be ordered factors?
- **num_levels**  
The number of factor levels to generate
- **fractional**  
Whether to generate times with fractional seconds
- **tz**  
The timezone to use for dates

**Examples**

\begin{verbatim}
# characters
gen_character(4)

# factors
gen_factor(4)

# logical
gen_logical(4)

# numbers
gen_double(4)
gen_integer(4)

# temporal data
gen_time(4)
gen_date(4)
gen_datetime(4)
\end{verbatim}

---

**gen_tbl**  
*Generate a random tibble*

**Description**

This is useful for benchmarking, but also for bug reports when you cannot share the real dataset.
Usage

```
gen_tbl(
  rows,
  cols = NULL,
  col_types = NULL,
  locale = default_locale(),
  missing = 0
)
```

Arguments

- `rows`: Number of rows to generate
- `cols`: Number of columns to generate. If `NULL`, this is derived from `col_types`.
- `col_types`: One of `NULL`, a `cols()` specification, or a string. See vignette("readr") for more details. If `NULL`, all column types will be imputed from the first 1000 rows on the input. This is convenient (and fast), but not robust. If the imputation fails, you'll need to supply the correct types yourself. If a column specification created by `cols()`, it must contain one column specification for each column. If you only want to read a subset of the columns, use `cols_only()`.
  Alternatively, you can use a compact string representation where each character represents one column: `c` = character, `i` = integer, `n` = number, `d` = double, `l` = logical, `f` = factor, `D` = date, `T` = date time, `t` = time, `?` = guess, or `/` to skip the column.
- `locale`: The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use `locale()` to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.
- `missing`: The percentage (from 0 to 1) of missing data to use.

Details

There is also a family of functions to generate individual vectors of each type.

See Also

- `generators` to generate individual vectors.

Examples

```
# random 10 x 5 table with random column types
rand_tbl <- gen_tbl(10, 5)
rand_tbl

# all double 25 x 4 table
dbl_tbl <- gen_tbl(25, 4, col_types = "dddd")
dbl_tbl

# Use the dots in long form column types to change the random function and options
types <- rep(times = 4, list(col_double(f = stats::runif, min = -10, max = 25)))
types
```
guess_type

dbl_tbl2 <- gen_tbl(25, 4, col_types = types)
dbl_tbl2

---

guess_type

Guess the type of a vector

Description

Guess the type of a vector

Usage

guess_type(
  x,
  na = c("", "NA"),
  locale = default_locale(),
  guess_integer = FALSE
)

Arguments

x          Character vector of values to parse.
na         Character vector of strings to interpret as missing values. Set this option to character() to indicate no missing values.
locale     The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use locale() to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.
guess_integer If TRUE, guess integer types for whole numbers, if FALSE guess numeric type for all numbers.

Examples

# Logical vectors
  guess_type(c("FALSE", "TRUE", "F", "T"))
# Integers and doubles
  guess_type(c("1","2","3"))
  guess_type(c("1.6","2.6","3.4"))
# Numbers containing grouping mark
  guess_type("1,234,566")
# ISO 8601 date times
  guess_type(c("2010-10-10"))
  guess_type(c("2010-10-10 01:02:03"))
  guess_type(c("01:02:03 AM"))
Description

A locale object tries to capture all the defaults that can vary between countries. You set the locale in once, and the details are automatically passed on down to the columns parsers. The defaults have been chosen to match R (i.e. US English) as closely as possible. See vignette("locales") for more details.

Usage

locale(
  date_names = "en",
  date_format = "%AD",
  time_format = "%AT",
  decimal_mark = ".",
  grouping_mark = "",
  tz = "UTC",
  encoding = "UTF-8"
)

default_locale()

Arguments

  date_names Character representations of day and month names. Either the language code as
    string (passed on to date_names_lang()) or an object created by date_names().
  date_format, time_format
    Default date and time formats.
  decimal_mark, grouping_mark
    Symbols used to indicate the decimal place, and to chunk larger numbers. Decimal
    mark can only be , or ..
  tz
    Default tz. This is used both for input (if the time zone isn’t present in individual strings), and for output (to control the default display). The default is to use "UTC", a time zone that does not use daylight savings time (DST) and hence is typically most useful for data. The absence of time zones makes it approximately 50x faster to generate UTC times than any other time zone. Use "" to use the system default time zone, but beware that this will not be reproducible across systems.
    For a complete list of possible time zones, see OlsonNames(). Americans, note that "EST" is a Canadian time zone that does not have DST. It is not Eastern Standard Time. It’s better to use "US/Eastern", "US/Central" etc.
  encoding
    Default encoding.

Examples

locale()
locale("fr")

# South American locale
locale("es", decimal_mark = ",")
Description

Read a delimited file into a tibble

Usage

```r
vroom(
  file,
  delim = NULL,
  col_names = TRUE,
  col_types = NULL,
  col_select = NULL,
  id = NULL,
  skip = 0,
  n_max = Inf,
  na = c("", "NA"),
  quote = "\\",
  comment = "\",
  trim_ws = TRUE,
  escape_double = TRUE,
  escape_backslash = FALSE,
  locale = default_locale(),
  guess_max = 100,
  altrep = TRUE,
  altrep_opts = deprecated(),
  num_threads = vroom_threads(),
  progress = vroom_progress(),
  .name_repair = "unique"
)
```

Arguments

- **file**: path to a local file.
- **delim**: One or more characters used to delimit fields within a file. If `NULL` the delimiter is guessed from the set of `c("", "\t", "", "|", ":", ";")`.
- **col_names**: Either `TRUE`, `FALSE` or a character vector of column names. If `TRUE`, the first row of the input will be used as the column names, and will not be included in the data frame. If `FALSE`, column names will be generated automatically: X1, X2, X3 etc. If `col_names` is a character vector, the values will be used as the names of the columns, and the first row of the input will be read into the first row of the output data frame.
- **id**: Missing (NA) column names will generate a warning, and be filled in with dummy names X1, X2 etc. Duplicate column names will generate a warning and be made unique with a numeric prefix.
col_types  One of NULL, a cols() specification, or a string. See vignette("readr") for more details.

If NULL, all column types will be imputed from the first 1000 rows on the input. This is convenient (and fast), but not robust. If the imputation fails, you’ll need to supply the correct types yourself.

If a column specification created by cols(), it must contain one column specification for each column. If you only want to read a subset of the columns, use cols_only(). Alternatively, you can use a compact string representation where each character represents one column: c = character, i = integer, n = number, d = double, l = logical, f = factor, D = date, T = date time, t = time, ? = guess, or _/- to skip the column.

col_select One or more selection expressions, like in dplyr::select(). Use c() or list() to use more than one expression. See ?dplyr::select for details on available selection options.

id Either a string or 'NULL'. If a string, the output will contain a variable with that name with the filename(s) as the value. If 'NULL', the default, no variable will be created.

skip Number of lines to skip before reading data.

n_max Maximum number of records to read.

na Character vector of strings to interpret as missing values. Set this option to character() to indicate no missing values.

quote Single character used to quote strings.

comment A string used to identify comments. Any text after the comment characters will be silently ignored.

trim_ws Should leading and trailing whitespace be trimmed from each field before parsing it?

escape_double Does the file escape quotes by doubling them? i.e. If this option is TRUE, the value ‘””’ represents a single quote, ‘”’.

escape_backslash Does the file use backslashes to escape special characters? This is more general than escape_double as backslashes can be used to escape the delimiter character, the quote character, or to add special characters like \n.

locale The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use locale() to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.

guess_max Maximum number of records to use for guessing column types.

altrep Control which column types use Altrep representations, either a character vector of types, TRUE or FALSE. See vroom_altrep() for full details.

altrep_opts Deprecated

num_threads Number of threads to use when reading and materializing vectors. If your data contains embedded newlines (newlines within fields) you must use num_threads = 1 to read the data properly.

progress Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option readr.show_progress to FALSE.
Handling of column names. By default, vroom ensures column names are not empty and unique. See `.name_repair` as documented in `tibble::tibble()` for additional options including supplying user defined name repair functions.

Examples

```r
# get path to example file
input_file <- vroom_example("mtcars.csv")

# Read from a path
vroom(input_file)

# You can also use literal paths directly
vroom("mtcars.csv")

## Not run:
# Including remote paths
vroom("https://github.com/r-lib/vroom/raw/master/inst/extdata/mtcars.csv")

## End(Not run)

# Or directly from a string (must contain a trailing newline)
vroom("x,y
1,2
3,4")

# Column selection -----------------------------------------------
# Pass column names or indexes directly to select them
vroom(input_file, col_select = c(model, cyl, gear))

# Or use the selection helpers
vroom(input_file, col_select = starts_with("d"))

# You can also rename specific columns
vroom(input_file, col_select = list(car = model, everything()))

# Column types --------------------------------------------------
# By default, vroom guesses the columns types, looking at 1000 rows
# throughout the dataset.
# You can specify them explicitly with a compact specification:
vroom("x,y
1,2
3,4", col_types = "dc")

# Or with a list of column types:
vroom("x,y
1,2
3,4", col_types = list(col_double(), col_character()))

# File types ---------------------------------------------------
# csv
vroom("a,b
1,0,0.2
", delim = ",")

# tsv
vroom("a\tb\n1.0\t2.0")

# Other delimiters
vroom("a\b\n1.0\t2.0", delim = "\")

# Read datasets across multiple files --------------------------
mtcars_by_cyl <- vroom_example(vroom_examples("mtcars-"))
```
vroom

mtcars_by_cyl

# Pass the filenames directly to vroom, they are efficiently combined
vroom(mtcars_by_cyl)

---

vroom_altrep

vroom_altrep()

vroom_altrep(c("chr", "fct", "int"))

vroom_altrep(TRUE)

vroom_altrep(FALSE)

---

vroom_altrep

vroom_altrep

Show which column types are using Altrep

Description

vroom_altrep() can be used directly as input to the altrep argument of vroom().

Usage

vroom_altrep(which = NULL)

Arguments

which A character vector of column types to use Altrep for. Can also take TRUE or FALSE to use Altrep for all possible or none of the types

Details

Alternatively there is also a family of environment variables to control use of the Altrep framework. These can then be set in your .Renviron file, e.g. with usethis::edit_r_environ(). For versions of R where the Altrep framework is unavailable (R < 3.5.0) they are automatically turned off and the variables have no effect. The variables can take one of true, false, TRUE, FALSE, 1, or 0.

- VROOM_USE_ALTREP_NUMERICS - If set use Altrep for all numeric types (default false).
- VROOM_USE_ALTREP_NUM
- VROOM_USE_ALTREP_LGL
- VROOM_USE_ALTREP_DATE
- VROOM_USE_ALTREP_TIME

Examples

vroom_altrep()
vroom_altrep(c("chr", "fct", "int"))
vroom_altrep(TRUE)
vroom_altrep(FALSE)
vroom_altrep_opts

Show which column types are using Altrep

Description

Deprecated This function is deprecated in favor of vroom_altrep().

Usage

vroom_altrep_opts(which = NULL)

Arguments

which A character vector of column types to use Altrep for. Can also take TRUE or FALSE to use Altrep for all possible or none of the types.

vroom_example

Get path to vroom examples

Description

vroom comes bundled with a number of sample files in its 'inst/extdata' directory. Use vroom_examples() to list all the available examples and vroom_example() to retrieve the path to one example.

Usage

vroom_example(path)

vroom_examples(pattern = NULL)

Arguments

path Name of file.

pattern A regular expression of filenames to match. If NULL all available files are returned. listed.

Examples

# List all available examples
vroom_examples()

# Get path to one example
vroom_example("mtcars.csv")
vroom_format

Convert a data frame to a delimited string

Description

This is equivalent to \texttt{vroom\_write()}, but instead of writing to disk, it returns a string. It is primarily useful for examples and for testing.

Usage

\begin{verbatim}
vroom_format(
  x,
  delim = "\t",
  na = "NA",
  col_names = TRUE,
  escape = c("double", "backslash", "none"),
  quote = c("needed", "all", "none"),
  bom = FALSE
)
\end{verbatim}

Arguments

\begin{itemize}
  \item \texttt{x} A data frame to write to disk
  \item \texttt{delim} Delimiter used to separate values. Defaults to \texttt{\t} to write tab separated value (TSV) files.
  \item \texttt{na} String used for missing values. Defaults to \texttt{NA}'.
  \item \texttt{col_names} Write columns names at the top of the file? Must be either \texttt{TRUE} or \texttt{FALSE}.
  \item \texttt{escape} The type of escape to use when quotes are in the data.
    \begin{itemize}
      \item \texttt{double} - quotes are escaped by doubling them.
      \item \texttt{backslash} - quotes are escaped by a preceding backslash.
      \item \texttt{none} - quotes are not escaped.
    \end{itemize}
  \item \texttt{quote} How to handle fields which contain characters that need to be quoted.
    \begin{itemize}
      \item \texttt{needed} - Only quote fields which need them.
      \item \texttt{all} - Quote all fields.
      \item \texttt{none} - Never quote fields.
    \end{itemize}
  \item \texttt{bom} If \texttt{TRUE} add a UTF-8 BOM at the beginning of the file. This is recommended when saving data for consumption by excel, as it will force excel to read the data with the correct encoding (UTF-8)
\end{itemize}
Description

Read a fixed width file into a tibble

Usage

vroom_fwf(
  file,
  col_positions = fwf_empty(file, skip, n = guess_max),
  col_types = NULL,
  col_select = NULL,
  id = NULL,
  locale = default_locale(),
  na = c("", "NA"),
  comment = "",
  trim_ws = TRUE,
  skip = 0,
  n_max = Inf,
  guess_max = 100,
  altrep = TRUE,
  altrep_opts = deprecated(),
  num_threads = vroom_threads(),
  progress = vroom_progress(),
  .name_repair = "unique"
)

fwf_empty(file, skip = 0, col_names = NULL, comment = "", n = 100L)

fwf_widths(widths, col_names = NULL)

fwf_positions(start, end = NULL, col_names = NULL)

fwf_cols(...)

Arguments

file Either a path to a file, a connection, or literal data (either a single string or a raw vector).
Files ending in .gz, .bz2, .xz, or .zip will be automatically uncompressed.
Files starting with http://, https://, ftp://, or ftps:// will be automatically downloaded. Remote gz files can also be automatically downloaded and decompressed.
Literal data is most useful for examples and tests. It must contain at least one new line to be recognised as data (instead of a path) or be a vector of greater than length 1.
Using a value of clipboard() will read from the system clipboard.
col_positions: Column positions, as created by \texttt{fwf_empty()}, \texttt{fwf_widths()} or \texttt{fwf_positions()}. To read in only selected fields, use \texttt{fwf_positions()}. If the width of the last column is variable (a ragged \texttt{fwf} file), supply the last end position as \texttt{NA}.

col_types: One of \texttt{NULL}, a \texttt{cols()} specification, or a string. See vignette("readr") for more details.

If \texttt{NULL}, all column types will be imputed from the first 1000 rows on the input. This is convenient (and fast), but not robust. If the imputation fails, you’ll need to supply the correct types yourself.

If a column specification created by \texttt{cols()}, it must contain one column specification for each column. If you only want to read a subset of the columns, use \texttt{cols_only()}.

Alternatively, you can use a compact string representation where each character represents one column: \texttt{c} = character, \texttt{i} = integer, \texttt{n} = number, \texttt{d} = double, \texttt{l} = logical, \texttt{f} = factor, \texttt{D} = date, \texttt{T} = date time, \texttt{t} = time, \texttt{?} = guess, or \texttt{-} to skip the column.

col_select: One or more selection expressions, like in \texttt{dplyr::select()}. Use \texttt{c()} or \texttt{list()} to use more than one expression. See ?\texttt{dplyr::select} for details on available selection options.

id: Either a string or "NULL". If a string, the output will contain a variable with that name with the filename(s) as the value. If "NULL", the default, no variable will be created.

locale: The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use \texttt{locale()} to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.

na: Character vector of strings to interpret as missing values. Set this option to \texttt{character()} to indicate no missing values.

comment: A string used to identify comments. Any text after the comment characters will be silently ignored.

trim_ws: Should leading and trailing whitespace be trimmed from each field before parsing it?

skip: Number of lines to skip before reading data.

n_max: Maximum number of records to read.

guess_max: Maximum number of records to use for guessing column types.

altrep: Control which column types use Altrep representations, either a character vector of types, \texttt{TRUE} or \texttt{FALSE}. See \texttt{vroom_altrep()} for full details.

altrep_opts: \texttt{Deprecated}

num_threads: Number of threads to use when reading and materializing vectors. If your data contains embedded newlines (newlines within fields) you \texttt{must} use \texttt{num_threads = 1} to read the data properly.

progress: Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option \texttt{readr.show_progress} to \texttt{FALSE}.

.name_repair: Handling of column names. By default, \texttt{vroom} ensures column names are not empty and unique. See .\texttt{name_repair} as documented in \texttt{tibble::tibble()} for additional options including supplying user defined name repair functions.
col_names Either NULL, or a character vector column names.

n Number of lines the tokenizer will read to determine file structure. By default it is set to 100.

widths Width of each field. Use NA as width of last field when reading a ragged ffw file.

start, end Starting and ending (inclusive) positions of each field. Use NA as last end field when reading a ragged ffw file.

... If the first element is a data frame, then it must have all numeric columns and either one or two rows. The column names are the variable names. The column values are the variable widths if a length one vector, and if length two, variable start and end positions. The elements of ... are used to construct a data frame with or two rows as above.

Examples

```r
fwf_sample <- vroom_example("fwf-sample.txt")
cat(readLines(fwf_sample))

# You can specify column positions in several ways:
# 1. Guess based on position of empty columns
vroom_fwf(fwf_sample, ffw_empty(fwf_sample, col_names = c("first", "last", "state", "ssn")))
# 2. A vector of field widths
vroom_fwf(fwf_sample, ffw_widths(c(20, 10, 12), c("name", "state", "ssn")))
# 3. Paired vectors of start and end positions
vroom_fwf(fwf_sample, ffw_positions(c(1, 30), c(20, 42), c("name", "ssn")))
# 4. Named arguments with start and end positions
vroom_fwf(fwf_sample, ffw_cols(name = c(1, 20), ssn = c(30, 42)))
# 5. Named arguments with column widths
vroom_fwf(fwf_sample, ffw_cols(name = 20, state = 10, ssn = 12))
```

vroom_lines Read lines from a file

Description

vroom_lines() is similar to readLines(), however it reads the lines lazily like vroom(), so operations like length(), head(), tail() and sample() can be done much more efficiently without reading all the data into R.

Usage

```r
vroom_lines(
  file,
  n_max = Inf,
  skip = 0,
  locale = default_locale(),
  altrep = TRUE,
  altrep_opts = deprecated(),
  num_threads = vroom_threads(),
  progress = vroom_progress()
)
```
Arguments

**file**  
path to a local file.

**n_max**  
Maximum number of records to read.

**skip**  
Number of lines to skip before reading data.

**locale**  
The locale controls defaults that vary from place to place. The default locale is US-centric (like R), but you can use `locale()` to create your own locale that controls things like the default time zone, encoding, decimal mark, big mark, and day/month names.

**altrep**  
Control which column types use Altrep representations, either a character vector of types, TRUE or FALSE. See `vroom_altrep()` for full details.

**altrep_opts**  
**Deprecated**

**num_threads**  
Number of threads to use when reading and materializing vectors. If your data contains embedded newlines (newlines within fields) you must use `num_threads = 1` to read the data properly.

**progress**  
Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option `readr.show_progress` to FALSE.

Examples

```r
lines <- vroom_lines(vroom_example("mtcars.csv"))

length(lines)
head(lines, n = 2)
tail(lines, n = 2)
sample(lines, size = 2)
```

**vroom_progress**  
**Determine if progress bars should be shown**

Description

Progress bars are shown unless one of the following is TRUE

- The bar is explicitly disabled by setting `Sys.getenv("VROOM_SHOW_PROGRESS"="false")`
- The code is run in a non-interactive session (`interactive()` is FALSE).
- The code is run in an RStudio notebook chunk.
- The code is run by knitr / markdown.
- The code is run by testthat (the TESTTHAT envvar is true).

Usage

```r
vroom_progress()
```

Examples

```r
vroom_progress()
```
**vroom_str**  
*Structure of objects*

**Description**

Similar to `str()` but with more information for Altrep objects.

**Usage**

```r
vroom_str(x)
```

**Arguments**

- `x`  
  a vector

**Examples**

```r
# when used on non-altrep objects altrep will always be false
vroom_str(mtcars)
```

```r
mt <- vroom(vroom_example("mtcars.csv"), ",", altrep = c("chr", "dbl"))
vroom_str(mt)
```

**vroom_write**  
*Write a data frame to a delimited file*

**Description**

Write a data frame to a delimited file

**Usage**

```r
vroom_write(
  x,
  path,
  delim = "\t",
  na = "NA",
  col_names = !append,
  append = FALSE,
  quote = c("needed", "all", "none"),
  escape = c("double", "backslash", "none"),
  bom = FALSE,
  num_threads = vroom_threads(),
  progress = vroom_progress()
)
```
Arguments

- **x**: A data frame to write to disk
- **path**: Path or connection to write to.
- **delim**: Delimiter used to separate values. Defaults to \t to write tab separated value (TSV) files.
- **na**: String used for missing values. Defaults to 'NA'.
- **col_names**: Write columns names at the top of the file? Must be either TRUE or FALSE.
- **append**: If FALSE, will overwrite existing file. If TRUE, will append to existing file. In both cases, if file does not exist a new file is created.
- **quote**: How to handle fields which contain characters that need to be quoted.
  - **needed**: Only quote fields which need them.
  - **all**: Quote all fields.
  - **none**: Never quote fields.
- **escape**: The type of escape to use when quotes are in the data.
  - **double**: quotes are escaped by doubling them.
  - **backslash**: quotes are escaped by a preceding backslash.
  - **none**: quotes are not escaped.
- **bom**: If TRUE add a UTF-8 BOM at the beginning of the file. This is recommended when saving data for consumption by excel, as it will force excel to read the data with the correct encoding (UTF-8)
- **num_threads**: Number of threads to use when reading and materializing vectors. If your data contains embedded newlines (newlines within fields) you must use num_threads = 1 to read the data properly.
- **progress**: Display a progress bar? By default it will only display in an interactive session and not while knitting a document. The display is updated every 50,000 values and will only display if estimated reading time is 5 seconds or more. The automatic progress bar can be disabled by setting option readr.show_progress to FALSE.

Examples

```r
# If you only specify a file name, vroom_write() will write
# the file to your current working directory.
out_file <- tempfile(fileext = "csv")
vroom_write(mtcars, out_file, ",")

# You can also use a literal filename
# vroom_write(mtcars, "mtcars.tsv")

# If you add an extension to the file name, write_() will automatically compress the output.
# vroom_write(mtcars, "mtcars.tsv.gz")
# vroom_write(mtcars, "mtcars.tsv.bz2")
# vroom_write(mtcars, "mtcars.tsv.xz")
```
