

### Solution to Series 5

1. a) Plot the data. Read in the data:

```
> paint <- read.table(file="http://stat.ethz.ch/Teaching/Datasets/paint.txt",header=TRUE)
> paint$SAMPLE <- as.factor(paint$SAMPLE)
> paint$BATCH <- as.factor(paint$BATCH)
> plot(paint$BATCH[paint$SAMPLE==1],paint$MOISTURE[paint$SAMPLE==1],col=2)
> points(paint$BATCH[paint$SAMPLE==2],paint$MOISTURE[paint$SAMPLE==2],col=5)
```

b) Write down the analysis of variance model. Why are all factors random?

$$Y_{ijk} = \mu + batch_i + sample_{j(i)} + \epsilon_{ijk}$$

$batch_i$  random effect of BATCH  $i$ ,  $batch_i \sim \mathcal{N}(0, \sigma_{batch}^2)$ ,  
 $sample_{j(i)}$  random effect of SAMPLE  $j$ ,  $sample_{j(i)} \sim \mathcal{N}(0, \sigma_{sample}^2)$ ,  
 $\epsilon_{ijk}$  measurement error,  $\epsilon_{ijk} \sim \mathcal{N}(0, \sigma_e^2)$ .

All factors are random because BATCHs are chosen at random from the population of batches and SAMPLEs are chosen from the population of all samples.

c) Construct the skeleton analysis of variance table with degrees of freedom and expected values.

Score	df	$E(MS)$
batch	14	$\sigma_e^2 + 2\sigma_{sample}^2 + 4\sigma_{batch}^2$
batch:sample	15	$\sigma_e^2 + 2\sigma_{sample}^2$
Residuals	30	$\sigma_e^2$
Total	59	

d) Calculate estimates for  $\sigma_{BATCH}^2$  and  $\sigma_{SAMPLE}^2$ . Compute the F test statistics, first by hand and then use R .

```
> mod1 <- aov(MOISTURE~BATCH/SAMPLE,data=paint)
> summary(mod1)
```

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
BATCH	14	1210.9	86.50	94.36	<2e-16 ***
BATCH:SAMPLE	15	869.7	57.98	63.26	<2e-16 ***
Residuals	30	27.5	0.92		

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

$$\hat{\sigma}_e^2 = 0.917$$

$$\hat{\sigma}_{sample}^2 = (57.983 - 0.917)/2 = 28.533$$

$$\hat{\sigma}_{batch}^2 = (86.495 - 57.983)/4 = 7.128$$

$$F_{\sigma_{batch}^2=0} = \frac{\hat{\sigma}_e^2 + 2\hat{\sigma}_{sample}^2 + 4\hat{\sigma}_{batch}^2}{\hat{\sigma}_e^2 + 2\hat{\sigma}_{sample}^2} = \frac{0.917 + 2 \cdot 28.533 + 4 \cdot 7.128}{0.917 + 2 \cdot 28.533} = 1.4917$$

$$F_{\sigma_{sample}^2=0} = \frac{\hat{\sigma}_e^2 + 2\hat{\sigma}_{sample}^2}{\hat{\sigma}_e^2} = 63.255$$

```
> mod2 <- aov(MOISTURE~BATCH+Error(SAMPLE%in% BATCH),data=paint)
> summary(mod2)
```

Error: SAMPLE:BATCH

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
BATCH	14	1210.9	86.50	1.492	0.226
Residuals	15	869.7	57.98		

Error: Within

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Residuals	30	27.5	0.9167		

## 2. a) Plot the data.

```
> peanut <- read.table(file="http://stat.ethz.ch/Teaching/Datasets/Peanut.txt",header=TRUE)
> peanut$Row <- as.factor(peanut$Row)
> peanut$Column <- as.factor(peanut$Column)
> peanut$Treatment <- as.factor(peanut$Treatment)
> par(mfrow=c(2,2))
> plot(Yield ~ Treatment+Row+Column, data=peanut)
```

b) Carry out the analysis of variance and report your findings.

```
> modP1 <- aov(Yield ~ Treatment+Row+Column, data=peanut)
> summary(modP1)
```

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Treatment	3	23.42	7.81	1.953	0.22255
Row	3	9.43	3.14	0.786	0.54394
Column	3	245.91	81.97	20.507	0.00148 **
Residuals	6	23.98	4.00		

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

We see that the factor Treatment is not significant.

c) Treatment 1 is the control treatment. Even though the anova F is not significant, do any of the other treatments have a significantly higher yield, if a one-sided test is used?

```
> TukeyHSD(modP1,"Treatment", conf.level=0.90)
```

Tukey multiple comparisons of means  
90% family-wise confidence level

```
Fit: aov(formula = Yield ~ Treatment + Row + Column, data = peanut)
```

```
$Treatment
      diff      lwr      upr      p adj
2-1  3.075 -0.9887413  7.138741 0.2320297
3-1  0.825 -3.2387413  4.888741 0.9334796
4-1  0.275 -3.7887413  4.338741 0.9971031
3-2 -2.250 -6.3137413  1.813741 0.4479925
4-2 -2.800 -6.8637413  1.263741 0.2914481
4-3 -0.550 -4.6137413  3.513741 0.9782233
```

If we look at the first three rows of the Treatment differences table we see that all of the confidence intervals of 2-1, 3-1 and 4-1 contain 0. So we can say that non of the one-sided tests are significant. That is, non of the other treatments have a significantly higher yield compared to the control treatment number 1.

The breeder decided to replicate the experiment. He used three blocks at different locations in the field, but in each location the north-south and east-west gradients were identified. The data are in the file Peanut2.txt.

- d) Which factors are nested, which are crossed? The factors Column and Row are nested in the factor Rep which represents the three different positions on the field.
- e) Give an analysis of variance table and test whether any pairwise differences are significant.

```
> peanut2 <- read.table(file="http://stat.ethz.ch/Teaching/Datasets/Peanut2.txt",header=TRUE)
> peanut2$Row <- as.factor(peanut2$Row)
> peanut2$Column <- as.factor(peanut2$Column)
> peanut2$Treatment <- as.factor(peanut2$Treatment)
> peanut2$Rep <- as.factor(peanut2$Rep)
> modP2 <- aov(Yield ~ Treatment+Rep/(Row+Column), data=peanut2)
> summary(modP2)
```

	Df	Sum Sq	Mean Sq	F value	Pr(>F)
Treatment	3	95.7	31.92	3.962	0.0199 *
Rep	2	15.8	7.92	0.983	0.3888
Rep:Row	9	66.1	7.35	0.912	0.5311
Rep:Column	9	530.8	58.97	7.321	4.55e-05 ***
Residuals	24	193.3	8.06		

---

Signif. codes: 0 '\*\*\*' 0.001 '\*\*' 0.01 '\*' 0.05 '.' 0.1 ' ' 1

```
> TukeyHSD(modP2,"Treatment", conf.level=0.90)
```

```
Tukey multiple comparisons of means
90% family-wise confidence level
```

```
Fit: aov(formula = Yield ~ Treatment + Rep/(Row + Column), data = peanut2)
```

```
$Treatment
```

	diff	lwr	upr	p adj
2-1	3.3666667	0.5619194	6.17141398	0.0363778
3-1	0.5000000	-2.3047473	3.30474732	0.9724701
4-1	-0.0666667	-2.8714140	2.73808065	0.9999296
3-2	-2.8666667	-5.6714140	-0.06191935	0.0899752
4-2	-3.4333333	-6.2380806	-0.62858602	0.0320424
4-3	-0.5666667	-3.3714140	2.23808065	0.9607866

We see that Treatment 2 is significantly better than the control.

3. Is the treatment with Motrin efficient? Is the washout period long enough or could there still be a carry-over effect?

Read in the data:

```
> tennis <- read.table(file="http://stat.ethz.ch/Teaching/Datasets/TENNIS.dat")
> names(tennis)=c("id", "age", "sex", "order", "max1", "twelve1", "ave1", "overall1",
"max2", "twelve2", "ave2", "overall2", "max3", "twelve3", "ave3", "overall3")
> head(tennis)
> for (i in 3:16)
  tennis[,i][tennis[,i]==9]=NA

> diff.max=tennis$max1-tennis$max3
> diff.max[tennis$order==2]==-diff.max[tennis$order==2]
> plot(diff.max)
> abline(h=0,col=2,lty=2)
```

```
> summary(diff.max)

Wilcoxon signed rank test with continuity correction

```
data: diff.overall
V = 1705.5, p-value = 0.0003242
alternative hypothesis: true location is not equal to 0
```

We see that the degree of pain while on Motrin significantly better than degree of pain on placebo for all four pain measurements.

Anova approach for max, ave, twelve and overall Example for max:

```
> tennis.max=reshape(tennis[,c(1:5,9,13)],varying=c("max1","max2","max3"),idvar="id", timevar="per
> tennis.max$Treatment[tennis.max$order==1 & tennis.max$period==1]="Motrin"
> tennis.max$Treatment[tennis.max$period==2]="Washout"
```

```

> tennis.max$Treatment[tennis.max$order==1 & tennis.max$period==3]="Placebo"
> tennis.max$Treatment[tennis.max$order==2 & tennis.max$period==3]="Motrin"
> tennis.max$Treatment[tennis.max$order==2 & tennis.max$period==1]="Placebo"
> tennis.max$Treatment=factor(tennis.max$Treatment)
> tennis.max$id=factor(tennis$id)
> tennis.max$sex[tennis.max$sex==9]=NA
> tennis.max$sex=factor(tennis$sex)
> levels(tennis.max$sex)=c("male","female")
> tennis.max$period=factor(tennis.max$period)
> mod1=aov(max~id+period+Treatment,data=tennis.max[tennis.max$period!=2,])
> summary(mod1)

Is there any carry-over effect?

If there is a lasting effect of Motrin, the treatment difference in group A is smaller than in group B, in other words the average response in group A is larger than in group B.

```

> mod2=aov(max~order,data=tennis.max[tennis.max$period!=2,])
